A MEETING of the General Council of the University of Glasgow was held on Wednesday, Nov. 27th, for the purpose of electing three assessors to sit in the University Court, as provided for in the recently passed Universities (Scotland) Act. Six candidates were duly nominated and seconded, and, on a show of hands, the voting was found to be as follows:—Dr. Hector C. Cameron, 128; Sir John Neilson Cuthbertson, 122; Mr. David Hannay, 120; Sheriff Guthrie, 81; Mr. Vary Campbell, 78; Dr. McVail, 66. A poll was demanded, and voting papers will therefore be issued to all members of Council at once.

ZENANA MEDICAL WORK IN INDIA.

THE accounts which reach us from time to time of the medical missionary work among the native women of India continue to show satisfactory progress, the old barriers of prejudice, religion, and caste being gradually broken down before the steady, persistent, and devoted work of those who have left the comforts of their English homes, and all that the word "home" implies, to labour among their less fortunate sisters in India. A large field offers itself in India for female medical practitioners, and we can imagine no nobler task for those ladies who have taken up the study and practice of medicine than the attempt to alleviate the bodily sufferings of the helpless native women of India, who are not allowed to be attended to by medical men. That this veritable missionary work often claims its victims is unfortunately too true, and we are grieved to hear of the death at Srinagar, after a short illness, of Miss Fanny J. Butler, L.K.Q.C.P.I., at the early age of thirty-nine. Miss Butler left England for India in 1880, where, as medical

Digitized by Google

missionary of the Church of England Zenana Missionary Society, she toiled for six years and a half at Bhagalpore, Bengal, and Calcutta. Latterly Miss Butler was stationed at Kashmir, doing good work; patients came to her for treatment in large numbers; and greatly owing to her energy a site had been procured and a Women's Hospital commenced at the time of her death.

THE DESTRUCTION OF REFUSE AT BRADFORD.

DESTRUCTORS for refuse have for some time past been in use at Bradford, but they have not sufficed for the destruction of all the house and other refuse which is produced in the town, and the proposal to erect additional furnaces has been opposed on account of some nuisance attending the use of the existing ones. In order to deal with this each furnace has now been fitted with "Jones's cremators" and "Horsfall's injectors," by means of which an increased blast has been obtained and the temperature raised from 500° to 900° F.; the "stuff" being continually burned at a white heat. The alteration has been mainly brought about by the efforts of Alderman Hardaker, chairman of the Sanitary Committee; and, on inspecting the results, it was found that all objectionable odour had been removed; there being, amongst other things, a complete cessation of the emission of noxious vapour by the chimney-shaft. Indeed, it was confidently felt that success had been attained, and that other towns were sure to follow in the wake of Bradford in this matter of the disposal of refuse, which is year by year becoming more and more pressing. Formerly all market refuse, including vegetables, putrid fish, and the like, was disposed of in the same way as the general refuse, but it caused nuisance; it is now taken to one of the destructor stations, passed through grinding mills, mixed with ashes, and converted into a manure, which farmers are allowed to take away without payment.

THE KNEE REFLEX.

DR. K. E. WAGNER contributes to the *Vrach* a lengthy paper containing an account of a number of observations he has made on the subject of the tendon reflex of the knee. He finds that in slight and moderate cases of fever the tendon reflex is as a rule diminished, but that as the fever passes off the reflex returns to normal, or, may be, becomes stronger than normal. In severe cases, however, where there is a good deal of excitement, the knee reflex is increased. Generally speaking, it may be said that the amount of knee reflex is a kind of index to the tone of the nervous system. Baths from 77° to 90° F. given to fever patients increase both the knee reflex and the muscular strength. Walking to such an extent as not to occasion fatigue also increases the reflex. Sleep and lying in bed, Dr. Wagner found, decrease the reflex and also the muscular strength.

THE POLLUTION OF THE AIRE.

A PRELIMINARY attempt has been made to deal with the serious and vexed question of the pollution of the river Aire, a conference having taking place at Leeds between the mayors and town clerks of Bradford and Leeds and the chairman of the Sanitary Committee of Leeds. The special object of the gathering was to see whether such friendly and concurrent action could not be undertaken by the two corporations as would avoid hostile controversy and litigation. In the end, it was decided that on the reconstitution of the sanitary committees of each borough the respective mayors should communicate to those bodies certain proposals which had been provisionally arrived at. If these should meet with general concurrence, a more formal meeting would be arranged with a view to secure the acquiescence of other local authorities whose districts border on or otherwise affect the river. We trust that this desirable attempt to rid the Aire of its grave state of pollution may meet with success.

ENGLISH PRACTITIONERS IN FRANCE.

NO reasoning will suffice to make the conduct of the French Government appear justifiable in requiring English medical practitioners, practising among their own countrymen in French territory, to pass French examinations—not even that of "M.D." in a letter recently published by a contemporary. There is no such narrowness in England, and we do not agree with "M.D." in thinking that English practitioners would start legal processes against French medical men practising in England under any circumstances analogous to those under which English practitioners practise in French resorts. English legislation is the first, as far as we know, to make honourable and generous international recognition of medical diplomas possible. The Republic, with its boast of liberty and brotherhood, should be before and not behind England in such a matter. What are liberty and brotherhood worth if they do not lead to the abolition of territorial and international jealousies among scientific and professional men of equal standing?

THE BRITISH PHARMACOPŒIA.

IT is satisfactory to note from the report of the Pharmacopœia Committee of the General Medical Council that, in spite of the shortcomings of the British Pharmacopœia of 1885, only 559 copies remain of the 29,000 which have been printed, and that in determining upon issuing a reprint, it has also been decided that an "addendum" should be prepared and issued in the course of next year. There will, undoubtedly, be much interest in this addendum, even though it has been recommended that "no new remedies are to be introduced into it except such as have met with general approval." This clearly expresses an earnest desire to restrict the addendum within reasonable limits, and it may be hoped that it will not lead to the resuscitation of remedies which have long been discarded. It is late in the day to criticise the Pharmacopœia of 1885, but still it may be remarked that it retained and reintroduced many substances which have long since passed from the realm of practical therapeutics.

THE HOUSING OF THE POOR.

AN important circular signed by Mr. Ritchie has been issued from the Local Government Board to the local authorities in the metropolis, and to urban as well as rural sanitary authorities, calling their special attention to the ample powers conferred upon local authorities by the Housing of the Working Classes Act (1885), the Nuisances Removal Acts, and other statutes, to remedy the evils caused by insanitary dwellings, to prevent houses being overcrowded in such a manner as to be prejudicial to the health of the inmates, and to secure the demolition of buildings which are either themselves unfit for human habitation or which, by reason of their situation, are the cause of other buildings being rendered insanitary. The word "nuisance" includes "any premises in such a state as to be a nuisance or injurious to health," and "any house or part of a house so overcrowded as to be dangerous or prejudicial to the health of the inmates." If, after due notice, a nuisance is not abated, the offender or offenders can be taken before justices, who are invested with large preventive and punitive powers. It is the duty of the medical officer of health to report in writing to the local authority any premises in his district offending against the Sanitary Acts.

Digitized by Google

The report should then be referred by the local authority to a surveyor or engineer, for the necessary action to be taken. The circular concludes by warning the local authorities of the grave responsibility which they incur if they neglect the duty cast upon them by the Legislature of exercising their large powers for the protection of the poor, who are unable themselves for the most part to enforce the observance by their landlords of the laws relating to public health.

THE HOSPITAL SUNDAY FUND AND NURSING ASSOCIATIONS.

THE Council of the Hospital Sunday Fund did well to refer the proposal of Canon Clarke to alter Law IV. to the General Purposes Committee. Canon Clarke would add district nursing associations to hospitals and dispensaries for participation in the Hospital Sunday Fund. It sounds very plausible that nursing associations should receive grants from a fund raised essentially for the benefit of the sick poor. But to make such an alteration of the law will be to take a new departure altogether, not likely to contribute to the peace and prosperity of the Fund. Nursing associations, unlike hospitals, are largely sectarian and denominational in character, some of them aggressively so. Apart from this feature of these associations some of them are further characterised by much mutual rivalry. There are few men who have studied the working of the Hospital Sunday Fund more closely, or advised it more wisely, than Sir Sydney Waterlow, and he seldom allows himself to speak in such strong tones of warning as those he used at the last meeting of the Council on this subject, as we report elsewhere. We entirely agree with Sir Sydney Waterlow, and we trust that Canon Clarke will not persist in pressing his resolution on the general meeting of constituents. Nurses, as a part of the hospital system, benefit by the Hospital Sunday Fund; but to extend the fund to nursing associations as such is to invite an indefinite number of motley institutions to share the Fund and to diminish its strength for the great purposes for which it exists. The Fund will not bear the attenuating process which Canon Clarke proposes to initiate, and the very attempt to apply it would endanger that harmony which has hitherto been the glory of the Hospital Sunday Fund. We shall be greatly surprised if the General Purposes Committee does not report against this proposal.

TUBERCULOSIS OF THE OVARY.

DR. WAGNER gives in the *Vrach* notes of a number of post-mortem examinations on phthisical patients collected with a view to ascertain the frequency with which the tuberculous process extends to the ovaries. He puts this at 5 per cent., and remarks that when the ovary is attacked the only parts that are found to be abnormal are those which are actually invaded by the tubercle. He was able to obtain cultures of Koch's bacilli from tuberculous ovaries. Frequently when no tubercular foci could be detected by the naked eye they were discovered by the microscope.

VACCINATION BY THE VICAR.

AT Eaton Bray, a village in South Bedfordshire, a parishioner, who believed in vaccination, but feared the dangers which he thought accompanied it, procured a supply of lymph for himself, and got the vicar to operate. The public vaccinator, Mr. Sandell of Leighton Buzzard, expressed himself willing to see the case and certify if the Board approved of his doing so. The Board have agreed. We should have thought vicars had enough on their hands without undertaking the duties of the public vaccinator.

CLAIRVOYANT "PHYSICIANS."

THE monthly bulletin of the State Board of Health of Connecticut, U.S., reports that the Supreme Court of Wisconsin has held that a "clairvoyant physician" is liable for failure to exercise the ordinary skill and knowledge of a physician in good standing practising in the vicinity, and not merely the ordinary skill and knowledge of clairvoyants. The decision in question rules that any professing medical expert who "accepts employment as a healer of diseases, but relies for diagnosis and remedies upon some occult influence exerted upon him, or some mental intuition received by him when in an abnormal condition, takes the risk of the quality of accuracy of such influence or intuition." This legal decision affords a singular commentary upon the condition of so-called medical practice in some parts of the United States. The State in this country takes no such care to protect those who may choose to consult "clairvoyant physicians," if there be any such practitioners in these islands.

TYPHOID FEVER IN THE STOCK EXCHANGE.

A LARGE number of cases of enteric fever is reported to have occurred among members of the Stock Exchange, according to a statement in a contemporary not less than thirty members having been attacked. The medical officer of health has presented a report, in which he states that the cause was not to be explained by any faults in the general sanitation of the building, and that there was a very strong presumption in his mind that these cases of fever might have had their origin in the noxious exhalations arising from the sewer ventilating shaft. The circumstances of the outbreak are not before us, and we have not, therefore, the material which would enable us to discuss it. We are of course familiar with such occurrences in relation to polluted milk or water-supply, conditions which, we have no doubt, have been fully considered. An outbreak of fever due to sewer emanations raises questions of so much importance in relation to our system of sewer ventilation that the report of the Streets Committee, to which the subject has been referred, will be awaited with interest.

THE DETECTION OF IRON IN ORGANIC TISSUES.

PROFESSOR ZALÉSKI of Tomsk observes that in order to detect the presence of iron in organic tissues these should be immersed in a solution of yellow sulphide of ammonium—watery or alcoholic,—of the strength of from 1 to 3 per cent., for from two minutes to half an hour. A dark colouration will then be obtained if there is only a small quantity of iron present, and a black one if there is much.

INSECTS IN DRUGS.

AT a meeting of the Chemists' Assistants Association some rather disquieting specimens were lately exhibited, demonstrating the existence of "insects and germs" in sundry pharmaceutical preparations and drugs. The first was a fair-looking sample of crushed linseed recently obtained from a large wholesale firm, and kept in a wooden cask with a wooden cover. The exhibitor gravely asked what would be the effect of applying a poultice containing "thousands of insects" to an open wound, especially if the poultice be made with hot instead of boiling water. The other specimens, from aconite root, nux vomica, and cantharides, are perhaps of less importance, as these substances are not employed in the crude state. In the present anxiety to detect microscopic germs and to render them innocuous, it is worth considering whether we are not in

Digitized by Google

danger of overlooking more obvious sources of infection. In the hunt for small deer a different lens is employed, and mental vision is thrown out of focus for larger game.

DESTRUCTION OF A FEVER HOSPITAL.

WE have learned with regret that the fever hospital which had been provided jointly by the Rochester and Chatham urban authorities has been destroyed by fire. The hospital was a comparatively new one, which had been erected on approved modern principles, and the loss must be a severe one. We trust, however, that it will be temporary only, and that the buildings were fully insured against fire. The removal of the sick was attended with difficulty, a number of them having to be lifted through windows broken for the purpose; but, with the aid of medical men from Chatham and Rochester, and of others who hurried to the spot on receiving news of the catastrophe, they were all safely housed a short time after the occurrence.

UNIVERSITY OF SYDNEY.

WE understand that Mr. W. Anderson, F.R.C.S., Dr. Johnson Symington, and Dr. H. St. John Brooks have been nominated by the British board of selection as candidates for the Challis Chair of Anatomy in Sydney University. The final selection, however, will be made by the University authorities, who will consider the claims also of any candidates who may apply to them directly from Australia or elsewhere.

THE GASTRIC JUICE IN SCURVY.

DR. BOTKIN, jun., writing in the *Ejenedělnaya Klinicheskaya Gazeta*, states that according to his observations the gastric juice is considerably altered in cases of scurvy—its general acidity, as well as the amount of hydrochloric acid, being lowered, and in severe cases there being sometimes a complete absence of free hydrochloric acid and also of pepsin. The quantity of ptyalin in the saliva appeared to be decreased. No abnormality could be detected in the movements of the stomach.

MEDICINE IN CHINA.

THE Medical College for Chinese at Hong Kong is evidently doing good work in instructing the native students in medicine. It is in charge of Mr. Cantlie, F.R.C.S., late of Charing-cross Hospital as Dean, and there is a full staff of English lecturers and about thirty students. We have recently seen the examination questions in anatomy and physiology, and they are quite up to the average standard of our examinations. Several candidates obtained 80 per cent. of the allotted marks.

ALLEGED DEATH FROM SULPHONAL.

THE *Medical Record* of New York (Nov. 23rd) reports a death after the use of two fifteen-grain doses of sulphonal, the doses being given an hour and a quarter apart. The fatal result, it is said, occurred, by apnœa, forty hours after the first dose.

FOREIGN UNIVERSITY INTELLIGENCE.

Beyrout.—Dr. Boyer of Lyons has been appointed to the chair of Therapeutics and Hygiene.

Florence.—Dr. F. Coppola of Messina has been appointed Extraordinary Professor of Materia Medica and Experimental Pharmacology.

Gratz.—A new and convenient building has long been wished for, but has hitherto been unattainable from lack of funds. Now, however, the sum of £80,000 has been voted for the purpose, and the new buildings will be commenced in the spring.

Greifswald.—In view of a recent order requiring all medical officers of the German Army to be able to ride, a riding school has just been opened in order that students may have facilities for obtaining the required instruction and practice.

Halle.—The Professorship of Surgery, vacant by the death of Professor Richard von Volkmann, is likely to be offered to Dr. Schede of Hamburg, who is a native of Halle.

Lisbon.—Dr. R. da Gama Pinto has been appointed to the newly created chair of Ophthalmic Surgery.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following eminent foreign medical men are announced:—Dr. Don Gabriel Pereda, Professor of Pathology in the University of Madrid; Dr. Julius Graetzer of Breslau; Dr. Richard von Volkmann, Professor of Surgery in the University of Halle, whose life and professional career are sketched in another column.

THE report on the composition and quality of the metropolitan water-supply during the month of October, by Messrs. Crookes, Odling, and Meymott Tidy, shows that of the 189 samples examined the whole were found to be clear, bright, and well filtered. Throughout October the supply of water to the metropolis continued to be of excellent and very uniform character. In respect also of its clearness, its degree of freedom from colour tint, and its minute proportion of matter oxidisable by permanganate, the October water-supply has well sustained the satisfactory character presented by the supply of the previous month. Dr. Frankland, in his analysis, states that taking the average amount of organic impurity contained in a given volume of the Kent Company's water during the nine years ending December, 1876, as unity, the proportional amount contained in an equal volume of water supplied by each of the metropolitan water companies and by the Tottenham Local Board of Health was: Kent, 1·1; Colne Valley, 1·6; Tottenham, 1·7; East London, 1·9; New River, 2·1; Chelsea, 2·8; West Middlesex, 3·0; Lambeth, 3·1; Grand Junction, 3·2; and Southwark, 3·7.

AT the last meeting of the Society of Antiquaries, on Nov. 28th, Dr. John Evans, F.R.S., President, in the chair, Henry Laver, Esq., M.R.C.S., F.L.S., of Colchester, was admitted as a Fellow of the Society, to which he was elected nearly two years ago. Amongst the many learned antiquarians of this country there are very few who have more worthily won the coveted and honourable title of F.S.A. than Mr. Laver, and we congratulate him on receiving so distinguished a recognition of his long and earnest labours in archæological research.

ENERGETIC MEASURES are being taken in Italy, under the new sanitary code, for the detection of unsound food and the punishment of its vendors. Within the month of November, in Rome alone, 58,839 chilogrammes of tainted edibles were seized, among them being 30,457 chilogrammes of rotten fruit, 9600 putrid portions of sheep, 5876 chilogrammes of other similarly decomposed mutton, and 1788 of beef, 3586 chilogrammes of vegetables, and 347 of mushrooms.

THE Royal Commission on Vaccination held a sitting on Wednesday, Lord Herschell in the chair. Dr. Cory, Director of the Animal Vaccine Station, Lamb's Conduit-street, and Dr. Charles Creighton were examined.

Digitized by Google

THE Prefect of Rome has announced by circular to all the syndics of the provinces that the Istituto Antirabbico, or institution for the treatment and prevention of rabies on the Pasteur system, is now in full working order under the direction of Professor Angelo Celli.

HERBERT W. PAGE, M.C. Cantab., Surgeon to St. Mary's Hospital, has been appointed an additional examiner for this term for surgical degrees at the University of Cambridge.

DENGUE FEVER is reported to be spreading in Greece, and at Athens more than 2000 persons are laid up with it.

Pharmacology and Therapeutics.

RANKIN AND BORLAND'S SENNA PODS.

THIS preparation we have found to give very satisfactory results. It is readily taken, and appears to be very efficient and thoroughly free from griping properties. In several cases of chronic constipation it has afforded sufficient relief. No difficulty has been experienced in administering this preparation to children.

LANGAARD ON CHLORALAMIDE.

Dr. Langaard of Berlin reviews in the *Therapeutische Monatsschrift* the present state of our knowledge of the action of chloralamide—one of the latest of the various hypnotics that have from time to time been recommended to the notice of the profession. According to most observers, the new drug is a less powerful hypnotic, weight for weight, than hydrate of chloral. Kny considers that 3 grms. of the amide is only equivalent to 2 grms. of the hydrate. The ordinary dose for healthy adults may be put down as from 30 to 45 grains. Women and delicate patients should be given decidedly smaller doses than strong men. According to Lettow's observations in Professor Mosler's clinic, the best way to give it is as an enema. Sleep comes on in from half an hour to three hours after the drug has been taken. Lettow found the time required to induce sleep was in twenty-nine cases one hour; in twenty-three cases, two hours; and in three cases, three hours; the duration of the sleep being four to six hours in seventeen cases, two to four hours in two cases, and two hours only in two cases. Chloralamide shows itself to the best advantage where the sleeplessness is of a purely nervous origin, but it is by no means useless in numberless cases where there is some definite affection—that is to say, if it be not accompanied by pain of too severe a character. It will, however, act when the insomnia is due to the lightning pains of locomotor ataxy, also when there is a moderate amount of cough, and in a number of mental affections which are not accompanied by any very considerable degree of excitement. It has proved serviceable in delirium tremens; and in one case of cardiac asthma—myocarditis due to arterio-sclerosis—Hagen and Hüfler believed that it produced a real amelioration of the disease. There is very little to be said as to any undesirable by-effects; as a rule these are very slight, and are confined to a feeling of drowsiness and fatigue, with headache and giddiness of slight amount and short duration; but, notwithstanding the belief entertained by most writers on the subject that chloralamide is devoid of all action on the respiration and circulation, Dr. Langaard was able to demonstrate, by a number of careful experiments on animals, that it makes the respirations shallow and diminishes the arterial tension, though more slowly than chloral hydrate. He therefore cautions medical men to be very careful in prescribing it in cardiac affections. It is best ordered an hour or more before going to bed, and may be taken as a powder, washed down with milk, water, or coffee, or in solution with syrup, or it may be dissolved in wine or beer.

BROMOFORM IN WHOOPING-COUGH.

Dr. Stepp, who some time ago reported considerable success in the treatment of whooping-cough by means of bromoform combined with spirit and syrup, has lately written another paper in which he gives his experience of the use of bromoform in a fresh series of cases, bringing the total number in which he has used the drug up to 100. Although many of the patients were very young infants, the treatment did not fail in a single case, nor was there any instance in which any disagreeable effects followed its employment. He now finds that the best way of prescribing it is alone in a teaspoonful of water, with which it does not mix, but falls to the bottom in the form of a button. Care must be taken that this button is really swallowed, and not allowed to remain in the mouth. When given in this way children take it readily enough, though when ordered in the form of a mixture they sometimes greatly dislike it. As to the quantity to be ordered, Dr. Stepp states that to a child of three or four weeks old he gives one drop three or four times a day, to children of two or three years old four or five drops three or four times a day, and to children of seven years of age as much as six or seven drops three or four times a day. The vomiting very soon stopped, and recovery took place in from two to four weeks. In consequence of the volatile nature of the substance, and of its tendency to decompose, it is advisable only to order a small quantity from the chemist at a time—say, forty-five drops. It is also needful to see that the liquid has not any red tinge showing the presence of free bromine. The nurse must be cautioned to keep it from sunlight, and to put the stopper in the bottle immediately after use.

ACETATE OF LEAD IN PNEUMONIA.

Professor Crocq of Brussels has found that a remedy which was formerly a good deal employed in pneumonia, but which has long fallen into complete disuse—viz., acetate of lead—is in many cases of great value. This remedy was prescribed, combined with opium, by Ritscher, and afterwards by Strecht, Leudet, and others. Nothnagel and Rossbach mention it in their handbook, but consider that it is useless in ordinary cases, though they recommend it where there is œdema of the lung and in the hæmorrhagic form of the disease. Professor Crocq, having prescribed the lead salt in a large number of cases, is convinced that it frequently reduces the heart beats as much as ten or fifteen per minute in a single day, and that it exerts an equally marked effect upon the temperature, the sputum, too, becoming less in quantity and less deeply tinged. Instead of producing constipation, it is far more likely to open the bowels; but, notwithstanding this action, there is no objection to prescribing it with a little opium in cases where diarrhœa is present, or, if preferred, trisnitrate of bismuth may be added instead of opium. Small doses are of very little use, the minimum quantity that should be ordered for an adult per diem being six grains, and this may sometimes be increased with advantage to as much as fifteen grains. This treatment may be continued for a fortnight without any symptoms of lead poisoning presenting themselves. Professor Crocq remarks that it may be given at all stages of the disease, but at the beginning in strong subjects, and when the pain is severe, its action is but slight, and so antimonials are to be preferred at that time. Where, however, resolution is delayed, where there is but little fever, where the patient is very weak, where there is enteritis or diarrhœa, and especially where the digestive organs will not tolerate antimony, acetate of lead is very valuable. Again, when the pneumonia is secondary to some other serious disease, and when the heart is acting insufficiently so that the pulmonary circulation is interfered with, as in Bright's disease, in organic affections of the heart, in drunkards and in old people, acetate of lead will sometimes work wonders; indeed, he considers that it is most valuable in serious cases. Of course it must sometimes be combined with alcohol.

HÆMOGLOBIN IN CHLOROSIS.

In a recent number of *Merck's Bulletin* three formulæ are given for the employment of hæmoglobin in chlorosis and anæmia. It is stated that the chemical form and combination in which iron exists in hæmoglobin is thought to be such as to make the iron particularly easy of assimilation; hence, the use of hæmoglobin as a chalybeate or iron-bearing medicament has been attempted in cases of disease where an atonic condition of the digestive tract impedes the assimilation of medicines. A special virtue of hæmoglobin is said to be that it does not cause constipation. On the other hand, it is worth remembering that the proportion of iron in hæmoglobin is very small, and that it is currently held that, when the colouring matter is not enclosed in the corpuscles, it is speedily eliminated from the system.

RECOLLECTIONS AND IMPRESSIONS
(MEDICAL, HYGIENIC, AND GENERAL)
OF THE
PARIS EXHIBITION OF 1889.

BY BENJAMIN WARD RICHARDSON, M.D., F.R.S.

(*Continued from p. 1078.*)

THE hygienic part of the Exhibition covered a large surface so to say, for practically it was to be seen in some detail everywhere. No fact was more remarkable than this proof of the advance of sanitation. The idea of health, with one or two conspicuous omissions, was omnipresent. The exhibitors of fabrics for clothing put health often before fashion, or combined the two, or made the fashion in some cases subservient to the health. The manufacturers of articles used in manual labours and in mechanical labours were charged with the same idea; and even amongst the ruder crafts—such as that of the blacksmith (a department of craftship which was well worth finding out, but which did not appear to be very much sought after)—there were some healthy improvements, especially in regard to furnaces and the construction of bellows, in both of which labour and time were saved and cleanliness secured.

Of necessity the model dwelling-house played its part in the show, several specimens of small model dwellings for the poorer folk having been built for inspection. To the industrious poor themselves these exhibits were, I think, not so fascinating as they once were, and as they are expected by the philanthropic world still to be. A change is coming over the minds of the masses in this respect, which is one of the most obvious signs of the democratic spirit of the age. The intelligent workman prefers now to look at the better-class house in which his more fortunate neighbour luxuriates rather than at the mere comfortable little cottage in which the bare necessities are ministered to and nothing more, and in which the sanitation, however perfect it may be in its way, is always staring the occupant of the dwelling in the face as if it were ever reminding him of the blessing of health which he is permitted to enjoy if he will only take advantage of it. So in these small model houses the work-a-day lookers-on did not express any exceeding content. They did not feast their sight on much beyond what they had got. They could afford to come to the Exhibition, many of them from long distances, and, as may be supposed, they found in these models nothing very novel, and often nothing better than that which, with many warm recollections, they had left behind them. It may be said that the visitors to the Exhibition were not exactly the class for whose benefit and instruction these buildings were erected, and that the models were rather intended to show to philanthropists generally how much sanitation could be concentrated on the smallest possible plot of ground in the smallest possible area enclosed in four walls, and with the fullest range of appliances for putting the largest family into the most limited cubic space compatible with healthy existence, and with some approach towards moral comfort. If this argument be admitted, it was not in the present case very successfully demonstrated. I certainly should not have allowed the models I saw an inch of ground in Hygeiopolis. I could discover no model that strictly deserved the name, or any improvement of architectural construction that deserved the credit of useful novelty. The rooms were small in all cases, were placed at awkward angles to each other, were not too well lighted, were bare of chaste decoration, were not specially well provided with the essential system of warming combined with ventilation so that the heat from the fires could be thoroughly utilised, and were not properly studied in respect to the roof so as to prevent the roof surface from absorbing any amount of heat during the summer and radiating any amount that may be artificially generated within the dwelling during the winter. In one cottage the whole of its surface in the upper floor was thrown into a large bedroom for the smaller members of the family, the long-pointed angular roof over their heads leaving nothing between the sleepers and the sky except a thin tile or slate lined with a case of wood not much thicker in substance; in fact, just the kind of roof which is most treacherous and most dangerous. There was, however, a good thing in the fitting of one, at least, of the so-called model dwellings, a fitting which would bear introduction into any house, large as well as small, and that was a fire-stove extremely simple of construction and economical in application. This stove, of rather elegant shape, was made of iron, and stood out some three feet from the chimney or flue with which it was connected by means of an iron pipe running from it at right angles into the flue. The stove was fed with fuel from the top, the fuel itself being coal in the form of dust, and above the stove passing along the upper surface of the iron pipe which extended into the flue there was a broad iron shelf on which plates and dishes could be put or any other kitchen utensils holding water or foods that required to be kept warm. Two bars on each side were convenient also for holding extra supports and for other purposes. This, described to me as a cottage stove, with a few more additions for an oven and a boiler—additions which could easily be adapted—would form a really excellent stove, applicable specially to small dwellings, and admitting of introduction into houses of large size.

I spoke in my last paper on the subject of the ambulance and the mode in which it was furnished with surgical appliances. It may be well to refer now to what may be called the hygiene of the ambulance system as represented in the latest great public exhibit in this department. I had the advantage of going through the department in company with my friend Dr. Danford Thomas, the able Coroner for Central Middlesex, who has paid great attention to the ambulance system in our country. We found a great many things here of practical moment, and much that was suggestive to the student and young practitioner of the Army Medical Service. There was one ambulance ward which was particularly suggestive as to the mode in which, under the emergencies of military service, beds could be improvised on which to lay the wounded. One bed or litter was exhibited made of trusses of straw with sheeting on the top and blankets and coverlet. Another framework for a bedstead was constructed out of rough wood-work — literally sticks — but so simply and firmly joined together as to become a really strong and convenient couch. In a third instance the frame was formed out of rough wood such as might be taken out of a timberyard or out of the railings of a common fence, and in this case a more workman-like structure was produced. In a fourth illustration the construction was carried out with materials of better quality, and in a manner much more like a frame-work from the hand of the carpenter or upholsterer. But in every instance the work was seen to be of a kind which any skilful hospital orderly could have carried out under the direction of the army surgeon, or by the surgeon himself if he had no assistance. The whole picture formed an excellent object lesson, which might with every advantage be introduced into our great medical schools and centres of medical learning. In another ambulance tent the different modes of placing the foods and medicines required by the sick or wounded were well displayed. In one the table holding these requirements was placed at the head of the bed, resting, in fact, on the framework at the head. In a second, the table was fixed at the foot of the bed, and a third at the side. It seemed to me that the position at the head of the bed was the most convenient and wholesome. The table was most out of the way in this position, the food was furthest removed from sources of impurity, and everything was within easy reach of the patient who was able to move and help himself, as well as of the nurse who might be in attendance.

In regard to the ambulance tent itself, there was little novelty. The material was of the ordinary quality of cloth stuff made as waterproof as possible, according to our present means of obtaining waterproof stuffs, but suggesting at the same time the necessity for considerable improvement in the manufacture of a lighter and easily portable material for temporary hospital purposes. In some of the ambulance tents (two of them, if my memory is correct) a ventilator was carried out ingeniously by the interposition of a kind of interspace curtained off in the angle of the roof. Into this space valvular openings permitted the air from the body of the tent to rise, and from the roof of the tent itself this air was permitted to escape by another and separate series of openings. The idea was to ventilate without creating draughts of air that would affect the patients. The admission of fresh air was mainly through the doors of the tent, but other openings

Digitized by Google

were also provided. The lighting, artificially, was by means of the mineral oil lamp, suspended from the cross-bars of the roof or from a central pole support, and the arrangements for cooking or warming foods, carried out in one corner or side of the tent, were fairly complete. On the whole, the ambulance system here represented, although good, was not by any means ideal, to which criticism it will perhaps be said that it was as good as could be expected in a time of actual warfare when everything must needs be rough and ready. That, to my mind, is bad teaching, and bad provision for necessitous periods, a badness which has too often been acted upon, and always with results of the most disastrous nature when it has been put to proof. It seems common sense itself that, when emergencies are foreseen, the time has come, not for those emergencies to be left to answer for themselves in the rough-and-ready way in which they are too often left, but for making the most careful prevision and provision to meet all emergencies with all the modern appliances of the most advanced art. I mean by this that the greater the emergency the readier should have been the best means for meeting it and for relieving the difficulties that may spring from it.

METROPOLITAN HOSPITAL SUNDAY FUND.

A MEETING of the Council of the Metropolitan Hospital Sunday Fund was held in the "Long Parlour" at the Mansion House on Friday, Nov. 29th, at 3 P.M., some thirty or forty gentlemen being present, including Sir Sydney H. Waterlow, Bart. (vice-president), Canon Fleming, Canon Ingram, the Rev. Dr. Allon, the Rev. E. E. Jenkins, M.A. (ex-president of the Wesleyan Conference), Mr. Alfred Cohen, and Mr. R. B. Martin. Letters regretting inability to attend were read from the Bishop of London, Mr. Alfred Willett, F.R.C.S., the Rev. Septimus Hansard, M.A., Professor Marks, Captain Arthur Palliser, the Rev. Joseph Toulson, and others. A resolution adding the name of Sir James Whitehead, the late Lord Mayor, to the Council was carried unanimously and amid cheers. The annual general meeting of the constituents of the fund was fixed for Wednesday, the 11th inst., at 3 P.M. Sir Sydney Waterlow moved the adoption of the report, the main features of which were published in our issue of last week. It was, he said, very satisfactory to find that the sum raised this year was the largest ever received. For that they were greatly indebted to Sir James Whitehead, and he felt quite sure that the present Lord Mayor would be equally anxious to achieve an equal success during his mayoralty. Although no large legacies had been left to the fund, the increased collections were a satisfactory feature, and he trusted that they would continue steadily to progress to the £100,000, which sum represented the annual needs of the hospitals. He was glad to say that no serious complaints had been received as to the distribution of the fund, and all the recipients appeared satisfied. Some applicants, after due investigation of their claims, had been refused participation in the distribution for good and adequate reasons. The Rev Canon Fleming in seconding the motion, said that the growing results of the Hospital Sunday collections were largely due to the efforts of the clergy, and he felt sure that those efforts would not be relaxed. The report was unanimously adopted. The secretary, Mr. Henry N. Custance, read a long letter from the Rev. Canon Erskine Clarke, Vicar of Battersea, giving notice of his intention to move at the forthcoming meeting of constituents a resolution in favour of admitting district nursing associations to a participation in the distribution and benefits of the fund, and asking the Council to lend their support to his proposal. Law IV. of the constitution of the fund reads as follows:—"Those hospitals and dispensaries only which are managed by a committee duly constituted, and which produce their printed reports with balance sheets duly audited for the last three years, shall be allowed to participate in the Fund." The Rev. Canon Clarke will move to add after dispensaries the words "and district nurses' associations." The Rev. S. B. Burnaby, Rector of Hampstead, and several other reverend gentlemen having spoken in favour of the suggestion, Sir Sydney Waterlow rose and pointed out that the acceptance of the proposal would seriously alter the whole constitution of the fund and would extend its scope and open the door to such an extent that the Council would be unable to close it in the face of the many similar claims which might and probably would be urged. The Hospital Sunday Fund had prospered because it was undenominational, and everyone knew that the various nursing institutions stood on quite a different footing from the hospitals and other medical charities which now participated. He begged and warned the Council to be careful before they introduced what might become an element of discord and difficulty into their work. After some further discussion, it was resolved to refer the subject for consideration to the General Purposes Committee. It was decided to recommend to the constituents that the first Sunday after Trinity, June 8th, should be Hospital Sunday next year, Canon Fleming expressing the opinion that it was about the best Sunday they could choose. The meeting concluded with a vote of thanks to the Lord Mayor, who, in reply, stated that nothing should be left undone by him to make the fund a success during his year of office.

THE EPIDEMIC OF INFLUENZA IN ST. PETERSBURG.

DURING the last three or four weeks an epidemic of influenza, which has assumed serious proportions, has been raging in St. Petersburg and some of the suburbs and neighbouring towns—Peterhof, Gatchino, and Cronstadt amongst others suffering severely, while up to the date of the last information Tsarskoë Selo had escaped. In the schools of all grades from a quarter to a half of the pupils and teachers have been absent; the military hospitals, too, are so crowded that many of the men have to be treated in the barrack rooms, and the ordinary drill is seriously interfered with. Business is carried on but very partially, owing to the number of principals and *employés* who are laid up. The medical men—that is, those of them who are so fortunate as to have escaped—are "run off their legs," and the chemists are doing a thriving trade, chiefly in the sale of quinine to the public, who have largely come to understand the value of that drug in influenza. It is stated that one pharmacy of moderate size sold as much as a pound of quinine in two days. Dried raspberries, too, are reported to be so much in favour that it is now impossible to procure any. In order, apparently, to make up to the public for the difficulty of procuring medical attendance, the lay press has taken upon itself to instruct the uninitiated in the medical aspects of influenza. Thus, one of the first of the daily journals gravely states that influenza is liable to be complicated with pleurisy, eczema, bronchitis, pulmonary phthisis, nephritis, otitis, catarrhal pneumonia, vaginitis, scabies, lymphadenitis, and soft chancre!

It is impossible to say how far the affection has spread by actual contagion. In some families only one member has been attacked, while in others every member has succumbed one after another. The period of incubation appears to be two days, and that of invasion a few hours only. This is marked by lassitude, headache, and rigors, and is followed by great prostration, weakness, articular pains, headache, and sometimes by giddiness or various nervous phenomena, such as hyperæsthesia. The temperature rises rapidly; it may be almost as high as 105°, but generally falls quickly, seldom remaining high more than from one to three days. So far as appears at present, there is always some slight enlargement of the spleen to be detected. Three main types of the disease have been distinguished—the purely neurotic, the catarrhal, and the gastric. Cases corresponding to the purely neurotic type are marked by severe neuralgic pains, which might be supposed to betoken the commencement of an attack of pleurisy, while the mucous membrane of the respiratory and digestive tracts is quite unaffected. This form has been very common, and has been at the commencement mistaken for typhoid. In the catarrhal form there is bronchial catarrh, running at the nose, and conjunctivitis, which may either come on simultaneously with the fever or after this has gone down, and which usually last for several days after the temperature has become

Digitized by Google

normal. In the gastric form there is sometimes severe vomiting, lasting for one or two days. With regard to complications which have been noted as occurring during the present epidemic, herpes of the lip and nose has been very frequent, and sometimes has been seen on the eyelids; erythema, roseola, and urticaria have also been seen; meningitic irritation and catarrhal pneumonia, too, are mentioned. The last-named complication has been the cause of the few deaths that have taken place. Many of the cases, on the other hand, have been very slight. Some relapses are reported as having occurred from five to seven days after convalescence; they were marked by a rise of temperature, rigors, and catarrh. The drugs most generally employed are quinine, acetanilide (of which 7½ gr. doses are ordered two or three times daily), antipyrin, salicylate of soda, and diaphoretics, which have proved very successful.

It may be remarked that owing to the frequency and severity of epidemics in Russia the disease has acquired the name of "Russian catarrh."

THE METROPOLITAN ASYLUMS BOARD.

AT the board meeting of Managers, held on Saturday, the 30th ult., a report of the Ambulance Committee to the General Purposes Committee, having reference to Section 6 of the Poor-law Act, 1889, was considered and its recommendations were adopted. As a result, the carriages belonging to the Asylum managers will be available for the conveyance of persons suffering from any dangerous infectious disorder to and from hospitals and other places, at a charge for each conveyance for the present of 5*s.*, a discretionary power being retained to remit the charge when deemed expedient in the interest of the public health. Any of the following diseases will be regarded as dangerous infectious disorders—viz.: "small-pox, cholera, diphtheria, membranous croup, erysipelas, the disease known as scarlatina or scarlet fever, and the fevers known by any of the following names: typhus, typhoid, enteric, relapsing, continued or puerperal;" also measles and such other "dangerous infectious disorders" as from time to time may require conveyance. It is laid down as desirable that a medical certificate setting forth the nature of the disease, and stating that the sufferer is fit to be removed, should be supplied to the Board's officers previously to the patients' removal. Persons may, under exceptional circumstances, be conveyed to or from places outside the metropolitan area, an extra charge being made for the same.

MEDICAL TRIALS.

MASON *v.* CHEVENS.

THIS was an action to recover damages for libel brought by Mr. W. Inglis Mason, a duly qualified surgeon practising at Sudbury, Suffolk, and also holding the office of parish doctor, against Mr. Chevens, the proprietor, publisher, and printer of a newspaper called the *South-West Suffolk Echo*, which circulates in the neighbourhood of Sudbury. The case was tried before Mr. Justice Cave and a special jury. The evidence showed that on Jan. 6th last a woman named Sharman told the plaintiff that her child was ill, and asked him to attend to it as parish doctor. The plaintiff told her that she must first obtain an order from the relieving officer, who could have been seen by walking a short distance occupying about three minutes. He also informed her that by subscribing 5*s.* she would be entitled to medical attendance by him for three months under a club system established in the place, which allowed subscribers for a very small sum to obtain medical relief for themselves or the whole family. The woman declined to pay the fee of 5*s.* and went away. The following day the child died, and the coroner's jury subsequently found that death was due to natural causes. The plaintiff was aware that Mrs. Sharman was living with a weaver, who was earning wages and was a pensioner and in a position to pay for medical advice, and that was his reason for refusing to see the child. The libel complained of was contained in an article published in the defendant's newspaper accusing the plaintiff of heartless conduct, and the defence was justification, and that the words complained of were fair and *bonâ-fide* comment. The jury found for the plaintiff, damages £20, and judgment was given accordingly.

THE CHARGE OF INTENT TO PROCURE ABORTION AT SELBY OAK.

THE secretary of the Medical Defence Union has favoured us with the subjoined account of this case.

At the last Worcestershire Assizes, a surgeon named Cuthbert was tried for having administered a noxious drug—to wit, ergot—with intention to procure abortion. Mr. Lawson Tait, the President of the Medical Defence Union, attended, with the intention of going into the witness-box as a witness for the defence, but after the prosecutrix had given her evidence, the case was stopped by the judge, it being obvious to everyone that her evidence was altogether fabricated and unreliable, and leaving little doubt that she had sent the ergot through the post to herself before accusing the surgeon. The prosecutrix had been a nurse at the Selby Oak Workhouse, and in that capacity she had had charge of the midwifery department, keeping the key of the surgery, and having the stock bottle of ergot in her possession. It was found that the label of the bottle which she alleged Mr. Cuthbert had sent to her was marked: "Ex. Ergot. Liq.," and it was pointed out that this is a very unusual abbreviation, and that doctors usually from habit write—"Ext." The stock bottle was produced, and the gold lettering on the bottle was found to be identical with the above, the abbreviation being the same in all the three words. The previous history of the woman was demonstrated to have been a very chequered one, and she has since become manifestly insane.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Lambeth.—Dr. Verdon, in the thirty-third annual report on the parish of Lambeth, discusses the question of the sufficiency of inspectors of nuisances in metropolitan districts, and he points out that whereas in one district a population of 9000 is deemed sufficient to demand the services of an inspector, one of no less than 105,000 is not considered too much in another district. Between these two extremes almost every conceivable arrangement is in force. It is notorious that in many London areas systematic and regular inspection is not performed as it should be, and it is quite clear that Lambeth, notwithstanding certain recent and trivial alterations, still lacks much in this respect. An able summary of the results of the Sheffield small-pox epidemic in its relation to vaccination is also submitted to the vestry, together with certain historical references to the subject. The mortality rate is calculated on an estimated population of 281,935, and this gives 18·1 deaths per 1000 living during 1888. The zymotic rate was 2·2 per 1000, the largest fatalities being due to diarrhœa, whooping-cough, measles, and diphtheria, the incidence of the several diseases on locality being indicated by plans, on which the occurrences of disease are indicated by dots. Diphtheria caused 103 deaths amongst Lambeth people, and the question of the origin of this disease is discussed in the report, with the result that Dr. Verdon feels convinced that defective drainage does contribute towards the prevalence of the disease. Half of the houses examined in cases of diphtheria exhibited obvious drain-defects, and we may hope that this proportion is in excess of that which obtains generally throughout the parish.

Holborn.—The general death-rate for this metropolitan district during 1888 was the lowest on record—namely, 16·1 per 1000, which represents a net gain in the year of 10,585 lives compared with the result which would have followed if the previous average rate had prevailed. Diphtheria shows a serious tendency to increase. This is an observation which applies to many urban, as opposed to

Digitized by Google

rural, populations; and it cannot be altogether due to altered and improved nomenclature. Dr. Septimus Gibbon discusses the question of tubercular diseases and phthisis at some length, with the result that an opinion is expressed adverse to the view that phthisis is solely caused by that which the reporter holds to be its least potent factor or accompaniment—namely, the microbe. The report of the departmental committee on phthisis, appointed by the Veterinary Department of the Privy Council, is also adversely criticised. Current sanitary work would appear to be carried on with some energy in the district, and in a few instances action was taken during the year under Torrens' Act.

St. Luke.—This portion of the metropolis did not compare unfavourably as regards its death-rate last year with a number of the large towns and cities of England, the corrected rate per 1000 living having been 21·54. Diphtheria has somewhat increased, but, apart from this, the more preventable of the zymotic diseases have shown improvement. Attention is given to the slaughter-houses and the cowsheds, and they are described as being in a satisfactory condition. Amongst other improvements more or less affecting public health, Dr. Yarrow mentions the completion of the coroner's court, new mortuary, and disinfecting chamber; and it is noteworthy that since that change was effected none of the 43 inquests that have been held took place at public-houses. This is a piece of experience that some other metropolitan areas may well bear in mind.

Finchley.—This favoured metropolitan suburb had, according to Dr. Turle's report, a death-rate of 12·4 per 1000 last year, the extremes being 9·7 at Church End and 14·9 at North Finchley; whilst the general death-rate for London's outer ring was 15·3. All the more important of the causes of death are discussed in the report, and indications are given as to their prevention. A lengthened account is also given of the sanitary work carried out during the year, both as regards such as is systematic and that which was taken on the occurrence of cases of infectious diseases. Action in this latter respect has fortunately included a first instalment of an isolation hospital; but the inadequacy of the accommodation provided has been shown by the inability to take in diphtheria cases whilst scarlet fever was also under treatment. The slaughter-houses, dairies, and bakehouses are stated to have been subjected to regular inspection.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5167 births and 3477 deaths were registered during the week ending Nov. 30th. The annual rate of mortality in these towns, which had been 18·3 and 18·2 per 1000 in the preceding two weeks, rose last week to 19·0. During the first nine weeks of the current quarter the death-rate in these towns averaged 18·0 per 1000, and was 2·8 below the mean rate in the corresponding periods of the ten years 1879–88. The lowest rates in these towns last week were 11·6 in Norwich, 13·7 in Portsmouth, 14·1 in Huddersfield, and 14·6 in Leicester. The rates in the other towns ranged upwards to 25·1 in Hull, 27·4 in Manchester, 30·3 in Sunderland, and 32·0 in Plymouth. The deaths referred to the principal zymotic diseases, which had been 342 and 353 in the two preceding weeks, declined again last week to 343; they included 85 from whooping-cough, 63 from scarlet fever, 61 from measles, 51 from diphtheria, 46 from "fever" (principally enteric), 37 from diarrhœa, and not one from small-pox. No death from any of these zymotic diseases was registered during the week in Blackburn, Norwich, or Huddersfield; while they caused the highest death-rates in Bolton, Plymouth, and Sunderland. Whooping-cough caused the greatest mortality in Leeds and Hull; scarlet fever in Sheffield, Bolton, and Plymouth; measles in Nottingham and Sunderland; and "fever" in Leeds, Brighton, and Cardiff. The 51 deaths from diphtheria in the twenty-eight towns included 33 in London, 6 in Salford, 3 in Plymouth, 2 in Liverpool, and 2 in Newcastle-upon-Tyne. Small-pox caused no death in any of the twenty-eight great towns. Only one small-pox patient was under treatment at the end of the week in the Metropolitan Asylum Hospitals, and not one in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and London Fever Hospitals at the end of the week was 1650, against numbers increasing in the preceding twenty-two weeks from 559 to 1620; 132 cases were admitted to these hospitals during the week, against 204, 176, and 152 in the previous three weeks. The deaths referred to diseases of the respiratory organs, which had increased in the preceding five weeks from 281 to 328, further rose last week to 345, but were 118 below the corrected average. The causes of 71, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Newcastle-upon-Tyne, Leicester, Blackburn, Bolton, and in seven other smaller towns; the largest proportions of uncertified deaths were registered in Halifax, Huddersfield, Sheffield, Hull, and Liverpool.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·8 and 20·6 per 1000 in the preceding two weeks, further rose to 21·0 in the week ending Nov. 30th; this rate exceeded by 2·0 the rate that prevailed during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 15·0 and 17·4 in Dundee and Perth, to 22·5 in Glasgow and 23·1 in Aberdeen. The 536 deaths in the eight towns showed a further increase of 9 upon the numbers in recent weeks, and included 21 which were referred to whooping-cough, 18 to measles, 13 to scarlet fever, 11 to diarrhœa, 9 to diphtheria, 8 to "fever" (typhus, enteric, or ill-defined), and one to chicken-pox; in all, 81 deaths resulted from these principal zymotic diseases, against 64 and 53 in the preceding two weeks. These 81 deaths were equal to an annual rate of 3·2 per 1000, which exceeded by 1·3 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 14 and 7 in the preceding two weeks, rose last week to 21, of which 4 occurred in Greenock and 3 in each of five other towns. The 18 deaths from measles showed a considerable increase upon recent weekly numbers, and included 13 in Edinburgh and 5 in Glasgow. The 13 fatal cases of scarlet fever, including 6 in Glasgow and 5 in Leith, also showed a marked increase upon the numbers in recent weeks. Five of the 11 deaths attributed to diarrhœa and 4 of the deaths from "fever" were returned in Edinburgh; and of the 9 fatal cases of diphtheria, 4 occurred in Glasgow and 2 in Leith. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 149 and 135 in the preceding two weeks, further declined last week to 121, but exceeded the number in the corresponding week of last year by 29. The causes of 56, or more than 10 per cent., of the deaths registered in the eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 26·3 and 24·2 per 1000 in the preceding two weeks, rose to 28·7 in the week ending Nov. 30th, and exceeded the rate in any week since the beginning of March last. During the first nine weeks of the current quarter the death-rate in the city averaged 25·3 per 1000, the mean rate during the same period being 17·4 in London and 22·1 in Edinburgh. The 194 deaths in Dublin showed an increase of 30 upon the number in the previous week; they included 11 which were referred to "fever" (typhus, enteric, or ill-defined), 5 to whooping-cough, 5 to diarrhœa, 4 to measles, 1 to diphtheria, and not one either to small-pox or scarlet fever. Thus the deaths from these principal zymotic diseases, which had been 19, 14, and 9 in the three preceding weeks, rose last week to 26; they were equal to an annual rate of 3·8 per 1000, the rate from the same diseases being 1·7 in London and 5·3 in Edinburgh. The deaths referred to "fever," which had been 13, 7, and 6 in the three previous weeks, rose again last week to 11; and the fatal cases of each of the other zymotic diseases exceeded the numbers returned in the previous week. The deaths of infants showed a marked decline, while those of elderly persons exceeded by 8 the number returned in the previous week. Six deaths from violence and 4 inquest cases were registered; and 59, or nearly a third, of the deaths occurred in public institutions. The causes of 18, or more than 9 per cent., of the deaths in the city were not certified.

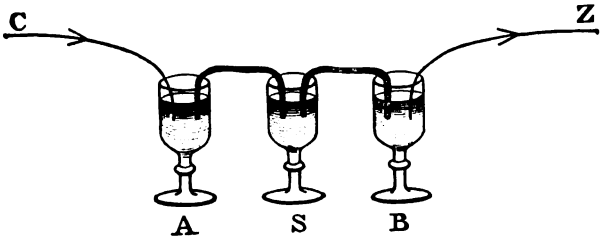
"Audi alteram partem."

THE TREATMENT OF CANCER BY ELECTRICITY.

To the Editors of THE LANCET.

SIRS,—In a recent paper in THE LANCET by Dr. J. Inglis Parsons on the treatment of cancer by electricity, he advocates the employment of shocks given by the interruption and reversal of very strong galvanic currents. I cannot help thinking that this mode of treatment is founded on unproven and probably fallacious theories; and is not free from danger to the patients.



Dr. Parsons advocates this mode of treatment on the theory that the low vitality of the cancer cells is extinguished by the sudden reversal of the current, and likens it to the process by which human life is destroyed by electricity. I have before argued[1] that electricity probably does not kill by shocks when administered to lowly organised living material, but only by the effects of shock when administered to highly organised living beings, and then by the shocks acting on the inhibitory nerves and interfering with the rhythm of the heart It is probable that it is more difficult to extinguish lowly organised vitality by shocks than highly specialised vitality presided over by an elaborate and finely differentiated nervous system. The experiments also brought forward by Dr. Parsons to prove that no change takes place between the poles when a current of electricity is applied to animal tissue have been proved to be fallacious. The experiments referred to are as follows:—"Three glasses were connected together with a stout lamp-wick. Into each of these a standard solution of iodide of potash was placed. A current was then passed through the solution, with an intensity of 200 milliampères, until the whole of the iodide of potash in the two outer glasses was decomposed. On testing the centre glass it was found to contain as much iodide of potash as before, although in the two outer glasses it was all decomposed." "A second experiment was then tried with water in the outer glasses, and a solution of iodide of potash in the centre. The current was passed as before, but no decomposition took place in the centre glass." Dr. Parsons goes on to say: "these experiments demonstrate in a conclusive way that the passage of a constant current does not cause any decomposition between the poles, although there must of necessity be an exchange of atoms between the molecules."

In referring to these experiments before the Obstetrical Society of London on June 21st, 1888, I stated that I had repeated the experiments[2], substituting pieces of copper wire for the lamp-wick as the connecting media. The copper wire, while being a very good conductor, was also decomposed by electricity. In this case the iodide of potassium was split up in each jar, free iodine appearing at the positive ends of the pieces of connecting wire, and a large quantity of gas (hydrogen) being liberated at the negative ends.

Some interesting experiments are also detailed in Golding-Bird's "Natural Philosophy,"[3] to show that changes do take place at other points than at the surface of the electrodes when a current of electricity is passed through several electrolytes.

"The statement that, in cases of electro-chemical decomposition, the changes which take place in the electrolyte are continuous through a line of molecules, and not limited to those in contact with the electrodes, meets with an interesting illustration in the well-known experiment in which an alkali appears to traverse an acid without combining with it, and which has been erroneously regarded as a case of suspension of the laws of chemical affinity.

"Let three cups—A, S, B—be placed side by side and connected by means of pieces of lamp-cotton, moistened with a solution of sulphate of soda. Let A and B be filled with a solution of this salt, and the central cup, S, with dilute sulphuric acid. Let a platinum electrode, C, connected with the last copper cell of the battery, dip into A, and another, Z, from the last zinc plate, dip into B. The positive current will now enter the fluid in A, and escape from B through Z, traversing S in its course. Electrolysis of the sulphate of soda will take place, its acid with oxygen being set free in A, and the sodium will pass through the sulphuric acid in S and reach B, so that a quantity of free

soda will soon be found in B, the sodium being oxidised at the expense of the water. It is evident that this alkaline body must have traversed the acid in S, with which, indeed, it for an instant combined, and the resulting sulphate of soda being decomposed by the current, the soda ultimately appears in B.

"That in experiments of this kind the base really combines with the acid it is made to traverse is proved by using a salt with the base of which the acid forms an insoluble combination. Under these circumstances it is removed from the influence of the current and does not reach the third cup. Place in A, B solutions of chloride of barium, and in S dilute sulphuric acid. On the current passing, the contents of A are decomposed, chlorine is evolved, and barium set free. This is conveyed in the manner before described to the middle cup, and here it is arrested in its course by the acid which, in combining with it, forms an absolutely insoluble salt, the sulphate of barytes, which falls to the bottom of the vessel, and then neither barium nor its oxide reaches the cup B. Hence the salt chosen for experiment must be one whose base forms a soluble combination with the acid in the middle cup."

It is difficult, in the present state of our knowledge, to say how many secondary electrolyses take place in the passage of the current through the body. That it meets several elements presenting different states of polarity towards each other is certain; but whether chemical change takes place at the points of junction of each of these heterogeneous bodies it is at present impossible to determine. As a rule, electrolysis does take place between any two substances of different electro-chemical polarity at the point where they touch one another, if they are capable of conducting electricity. If, in the treatment of a uterine fibroid, we use an external potter's clay electrode, a water rheostat to regulate the current, and an intra-uterine electrode, we know that electrolysis takes place at four points: (1) In the cells of the battery; (2) in the water in the rheostat; (3) between the clay and the skin of the patient; and (4) at the point where the internal electrode touches the mucous membrane of the uterus. That electrolysis does take place in the tissues is probable from the fact that storage of electricity takes place in a patient subjected to electrolytic treatment. The patient becomes a secondary battery, and is capable of giving off a current in an opposite direction to the one used from the primary battery. This can be demonstrated by disconnecting the rheophores from the battery immediately after an application of electricity has ceased and uniting them to each other, still keeping them connected to the electrodes in contact with the patient; a reverse current will immediately be shown on the galvanometer, at first about twelve milliampères, but rapidly decreasing to eight and four. No storage of electricity could take place unless some decomposition of the fluids contained in the tissues electrolysed had taken place. The liquids bathing the cell elements of the tissues must become split up, and their constituents accumulated on the opposite surfaces of contiguous tissue cells. It is this only that could produce a polarising current. Becquerel and Faraday have shown that polarisation results from the decomposition caused by the passage of the current.

In the recent discussions on the electrolysis of fibroid tumours it has been asked: If the passage of an electric current has an effect upon the tumour, how is it that the normal structures, such as the bladder, muscles, skin, adipose tissue, &c., which are included between the two electrodes, are not also affected? It is quite possible that they are affected, that in them the normal tissue changes

[3] Pp. 292, 293.

Digitized by Google

always in progress are accelerated, and that assimilation or "progressive metamorphosis" is encouraged. This from analogy would appear to be the case, for when a galvanic current is applied frequently to an atrophied and palsied muscle very often its nutrition is improved and its bulk increased; and there is no doubt that an increase takes place in the subcutaneous adipose tissue of the abdominal walls in patients subjected to the electrolytic treatment for fibroids.

The theory which Dr. Inglis Parsons first suggested, that the electric current may have a modifying influence on the cells of a tumour, which from their lower vitality could not recuperate themselves so well as the normal cells of the body, is not improbable. In fact, it may be that in the tumours subjected to a current of electricity a "retrograde metamorphosis" is set up.

Dr. Neftel, who is a great authority on the treatment of cancer by electricity,[4] "is inclined to believe that electrolysis produces remote constitutional effects by altering the condition of the protoplasm of the cells in which the poison of cancer is contained, and by the propagation of which the disease becoms constitutional. As soon as the protoplasm has, by the electrolytic process, lost its specific contagious qualities, the cancer is prevented from reproducing itself, and gradually disappears through the process of absorption."

Electrolysis is no doubt sometimes very useful in cancer, especially in cancer of the uterus, not only to destroy portions of the growth, and thus check the advance of the disease, but noticeably to diminish the pain and hæmorrhage so frequently attending it.—I am, Sirs, yours, &c.,

Dec. 3rd, 1889. W. E. STEAVENSON, M.D.

A CASE OF PTOMAINE POISONING.

To the Editors of THE LANCET.

SIRS,—Will you be good enough to allow me space to reply to the criticisms on a case of ptomaine poisoning which was kindly read for me in my absence by Dr. Barlow at the last meeting of the Clinical Society, more especially as some of the statements made were allowed to pass without protest? Dr. Sydney Martin is reported in THE LANCET to have said that "all those ptomaines which had been isolated had an action directly opposite to atropine, and no ptomaine was known which acted like that drug;" in other journals the report reads that "ptomaines, which were definite compounds, always gave rise to symptoms the opposite of atropine, and atropine was their antidote." Both statements seem to me to be open to criticism. Zuelzer and Sonnenschein[1] obtained from putrefying meat infusion an alkaloid which had the chemical reactions of atropine, and caused dilatation of the pupil with loss of light reflex, acceleration of the heart, and paralysis of the muscular coat of the intestines. Von Anrep obtained from salted sturgeon which had caused poisoning and from the bodies of those who died of the poison an alkaloid which produced the following symptoms: dilatation of the pupils, dryness of the mucous membranes, retention of urine and fæces, laboured breathing, feebleness of the heart's action, considerable pallor of skin and diminished temperature.[2] In man there were in addition paralysis of accommodation and difficulty in swallowing. I acknowledge that these are not in every respect the symptoms of atropine poisoning, but the resemblance is sufficiently striking to have caused one authority (Dr. Lauder Brunton) to insist on their mainly atropine-like character, and another (Professor Kobert)[3] to name the alkaloid "ptomato-atropine." Dr. Lauder Brunton[4] says: "Most of the alkaloids which have been obtained by the decomposition of albumen appear to belong to the muscarine type, and to have a tendency to cause diarrhœa, although some appear to belong rather to the atropine type, which to a certain extent counteracts the effects of muscarine,"—a statement repeated by Sir W. Aitken.[5] Moreover, Dr. Brunton[6] proposes to treat poisoning by a ptomaine having a purely atropine-like action with physostigma, and mentions a case in which this has been done. It is incorrect to say that "all those ptomaines that had been isolated had an action directly opposite to atropine," or that "atropine was their antidote." Leaving out of consideration the non-poisonous ptomaines, such as neuridine, cadaverine, putrescine, gadinine, and others, which Dr. Martin's statement does not cover, we find many well-defined ptomaines whose action is not directly opposite to atropine. Peptotoxine[7] causes in rabbits paralysis of the posterior extremities, somnolence, inability to stand, and death. Hydrocollidine[8] causes in birds tremors, violent convulsions, tetanic contractions, and death. Methyl-gadinine,[9] extracted from putrid horseflesh, produces symptoms like those of curare. Tetanine and tetanotoxine,[9] formed in the cultivation of the bacillus of tetanus, cause the symptoms of tetanus. The list might be much prolonged.

To return to my case, the symptoms closely resembled those of atropine and ptomato-atropine poisoning, and it was this resemblance, together with the almost sudden and practically complete recovery on evacuation from the bowel of two putrid-smelling motions, that induced me to describe it as a case of ptomaine poisoning. At the same time I am quite conscious of the gap that exists in the logical proof of this position—viz., absence of any demonstration of a ptomaine. The patient had no sign of kidney disease before his illness, and has had none since. Not only so, but the urine passed after thirty-four hours of suppression, and during the persistence of the symptoms, was free from either albumen or blood. To my mind these facts absolutely negative a diagnosis of uræmia.

I am, Sirs, yours obediently,

Dec. 2nd, 1889. C. SCOTT WATSON.

"INGUINAL COLOTOMY": A NOVEL METHOD OF PERFORMING THE OPERATION.

To the Editors of THE LANCET.

SIRS,—Dr. Purcell, in his paper on "Inguinal Colotomy for Malignant Diseases of the Rectum," describes an operation as now performed by him, and in the last paragraph he says "this operation was the outcome of deliberations between us"—viz., himself and me, "and I have to thank him" (Mr. Jessett) "for his suggestions, which I was enabled to carry out with the utmost success, and which we have styled 'A novel method of inguinal colotomy.'" As the method I have suggested, and which I described to the Fellows of the Medical Society, differs in many important particulars from that described by Dr. Purcell, I will ask you kindly to insert a description of my operation, which I have called "A novel method of performing the operation." The points in which my operation differs from that described by Dr. Purcell are as follows: 1. I make the ordinary incision through the abdominal parietes, *not a curved incision.* 2. I only clamp the intestine in one place—viz., as high up as I can. 3. I use catgut sutures, not silk, for bringing together the serous coats of the invaginated ends of the divided intestine. 4. I bring the upper or proximal portion of the intestine out of the wound for some three inches, and invaginate the divided end. *I do not fasten the cut ends of the upper segment to the wound.* The three cases described by Dr. Purcell were the first that came into the hospital after I had determined to divide the sigmoid flexure at the time of operating, and *invaginate* the cut end of the lower segment into itself and return it into the abdominal cavity. In operating on these cases Dr. Purcell most kindly carried out my suggestion, which is the only novelty in the operation so far as I had then gone. It was obvious, however, that there were grave objections to leaving the upper end of the intestine open. I determined, therefore, in my next cases to draw as much of the sigmoid flexure out of the wound as I could, divide it about three inches from its origin, and invaginate the cut ends of *both* segments, dropping the lower segment into the abdominal cavity, and leaving the upper segment protruding from the wound to be removed later on. In this consists the novelty of the operation. I showed at the Society a portion of the intestine which I had removed three days after operation, the invaginated end of which was firmly united. I may say the idea of this operation was the outcome of experience gained in my experimental work on intestinal surgery.

The operation as described by me to the Fellows of the Medical Society was as follows:—The patient should have

Digitized by Google

only liquid diet—strong beef-tea, eggs, milk &c.—for a week or ten days before the operation. The bowels should be kept well opened for some three or four days before by castor oil or some saline aperient, and the rectum washed out as far as possible once a day with warm water enemata.

Operation.—The abdomen being opened by a straight incision in the usual position, a small flat sponge with a long string attached to it is passed into the cavity to keep the small intestines and omentum from protruding; the index finger of the left hand is then passed backwards along the brim of the pelvis until it reaches the sacro-iliac synchondrosis, when the descending colon will usually be felt dipping into the pelvis; the finger is then passed over the colon, and a portion of the sigmoid flexure hooked up into the wound, and a loop some inches long withdrawn through the opening. A band of indiarubber is now to be passed through the mesocolon and fastened tolerably firmly round the intestine as high up as possible, to prevent the passage of its contents when the intestine is divided. The wound is next packed with small sponges, to each of which a long string should be attached, and the loop of intestine is surrounded with cotton-wool pads soaked in warm and carbolised water. The intestine is now cut across with scissors about three inches from its upper end, and the contents, if any, evacuated, in some cases it will be desirable to wash the gut out with warm carbolised water. All bleeding points being secured, the divided end of the lower segment is to be invaginated into itself and the end closed by a continuous catgut suture passing through its serous and muscular coats. The mesocolon may now be torn downwards for an inch or more if necessary, and the torn edges stitched over with fine catgut suture. This portion of the flexure is then allowed to drop back into the abdominal cavity. The divided end of the upper portion of intestine is next invaginated and secured in place by means of a continuous catgut suture and the indiarubber band removed. All sponges and wool-packing can now be removed and the parts thoroughly washed, and the parietal wound closed in the usual manner, care, however, being taken that the suture just above the intestine should pass through its serous and muscular coats, and the suture below is passed through the meso-colon. Two fine silk sutures are to be passed through the muscular and serous coats of the intestine and the abdominal parietes on each side, so as to thoroughly secure it from slipping. Finally, the spur of intestine, about three inches long, which is left protruding from the wound, is packed carefully round with thymol gauze, the whole covered with a thick pad of cotton-wool and a many-tailed flannel bandage lightly applied. The dressings should not be disturbed for three or four days unless symptoms occur necessitating their removal. On the fourth or fifth day the spur may be cut away on a level with the skin, all bleeding points secured, and the wound dressed with eucalyptus or boracic ointment. One great trouble to be feared in Allingham's operation, and the one I am describing, is the tendency of retraction of the stirrup of intestine when the loop or spur is cut off. I therefore in future shall content myself with opening the spur on the fourth or fifth day, and delay its total removal until some days later. This would have the further advantage of enabling the wound to be kept quite free from contamination from the escaping fæces.

I am, Sirs, yours faithfully,

FRED. BOWREMAN JESSETT.

Upper Wimpole-street, December, 1889.

DR. RENTOUL'S SCHEME.

To the Editors of THE LANCET.

SIRS,—As chairman of the meeting at Bethlem Hospital, referred to in Mr. R. H. S. Carpenter's letter in your last issue, I shall be glad if you will allow me to make some remarks in answer. Mr. Carpenter is mistaken on one or two points. The meeting was one of the South London District of the Metropolitan Counties Branch of the British Medical Association, and was summoned at the instance of the committee of that district for the purpose of obtaining the opinion of members of the district on the proposal of Dr. Rentoul, a course which was subsequently approved by a meeting of the council of the branch. On this occasion no general invitation was issued to the practitioners of the south of London.

The members of the Association were not outnumbered by visitors. There were seventeen members present, including the chairman and secretary, and only seven whose names are not on the list of the Branch. In reference to the proceedings, I can only say that, as chairman, I was bound by the rules of the district, one of which is to the effect that the chairman shall invite all visitors to express their opinions; but another prohibits voting by any but members of the Branch. It would clearly be against the spirit of that rule to allow any visitor to propose a resolution which he could not support by a vote. Such regulations do not seem to me peculiar to the British Medical Association. No Society or Association could allow its visitors—however free to speak—to vote, and thus control the action of that Society. But I can assure Mr. Carpenter that there was no attempt to hoax anyone, and I quite fail to see how the meeting can be so regarded. I am, Sirs, yours faithfully,

FREDERICK TAYLOR,
Vice-President of the South London District.

St. Thomas's-street, S.E., Nov. 30th, 1889.

To the Editors of THE LANCET.

SIRS,—The meeting at Bethlem Hospital on Nov. 13th to which Mr. Carpenter refers was a meeting of the South London District and not of the whole Metropolitan Branch, as might be inferred from Mr. Carpenter's letter. As mover of the amendment in favour of Dr. Rentoul's proposals, I wish to point out that it was by no means in the interests of our party that the voting was restricted to members of this Branch of the Association. The chairman and secretary, who both opposed Dr. Rentoul's proposals, were responsible for the enforcing of this bye-law of the Branch. For my own part, I thought that it would have been in better taste if the chairman had left this rule in abeyance in case no member insisted upon it. Mr. Carpenter must remember that a bye-law of the Metropolitan Branch, while allowing visitors to join in the discussions, forbids their voting.

As a special meeting of the whole Metropolitan Branch will shortly be held, and as the same rule is liable to be enforced, I would suggest that the above bye-law should be left in abeyance. I think I can say that there will be no objection to this on behalf of Dr. Rentoul's supporters. As a matter of fact, if anyone present at these meetings chooses to vote, there are never, so far as I know, any steps taken to test the right to do so. No doubt the proposer and seconder of a resolution run the risk of being challenged; and it is certainly irregular for anyone but a member to vote.

As to Mr. Carpenter's sneer at the officials of the British Medical Association, I beg to remind him that they have no power to set aside existing rules of the Association.

I am, Sirs, yours faithfully,

Highgate, N., Nov. 30th, 1889. HUGH WOODS, M.D.

THE PATHOLOGY OF CHOREA.

To the Editors of THE LANCET.

SIRS,—I trust that you will allow me to reply briefly to some of the criticisms of Dr. Maclagan upon the paper in which I suggested that the clinical associations of chorea point to the possibility of its origin in some temporary overgrowth of connective tissue in the nerve centres. Dr. Maclagan asks what evidence there is that rheumatism is capable of producing increased growth of connective tissue. Of its power of doing so I would quote the subcutaneous rheumatic nodules as standing examples, for they have been repeatedly shown to consist of connective tissue in a state of active growth. Dr. Maclagan adds that few pathologists are likely to endorse the view that the lesions of endocarditis are analogous with those which result in nodule formation; yet this view is supported by the results of microscopic research, and since it was first enunciated by Drs. Barlow and Warner in 1881 has gained wide acceptance. Nor can I see that it is in any way disproved by the so frequent limitation of the endocardial process to the valves, and to certain portions thereof; for although, with all respect to the opinion of Dr. Maclagan, I am not prepared to agree entirely with his views as to the influence of strain, I should be the last to deny that mechanical influences play a very important part in determining the distribution and seat of rheumatic lesions either in the joints or heart. If the clue to the association of chorea with rheumatism lies in the fact that one is a disease of the motor apparatus, the other of the motor centres, we might surely expect to

Digitized by Google

trace a similar association of chorea with gout and rheumatoid arthritis, in spite of the rarity of these maladies in early life. Unquestionably the undoubted occurrence of non-rheumatic chorea offers a very serious objection to the hypothesis suggested in my paper, if it can be shown that temporary fibrous tissue overgrowth is pathognomonic of rheumatism; but I do not think that it is proved that similar changes are not produced in other diseases, even although they may not result in the formation of subcutaneous nodules in the characteristic situations. In conclusion, I may say that I would not for a moment deny that the hypothesis at present rests upon slender foundations, but I believe that the clinical considerations upon which it is based warrant the suggestion of a line of pathological research. I am, Sirs, yours faithfully,

Chandos-street, W., Dec. 2nd, 1889. ARCH. E. GARROD.

"MEAN DURATION OF LIFE."

To the Editors of THE LANCET.

SIRS,—Parkes gives the following formula for calculating the mean duration of life, and at the same time condemns this quantity as a test of the health of the population considered: ⅔ inverse of death-rate + ⅓ inverse of birth-rate. This, when the birth-rate equals the death-rate, coincides with the formula quoted by Mr. S. C. Waters—viz., the inverse of the death-rate. The figures in Dr. Corfield's report do not agree with either of these formulæ, so that, as he asserts that he gives the real average duration of life calculated from the death-rate of his district, and not, as you suggested, the average age at death, it would be interesting to know the method used by him. The expression "mean duration of life" is, I hear, avoided by actuaries, but much affected by political and social orators and writers. Nothing puts an audience into a better frame of mind than telling them the mean duration of life has been increased. If it is taken to mean, as Mr. Waters suggests, the expectation at birth, it is essentially yearless, and quite unfit to be employed as a test of health in any particular year. I think two things are necessary in the proper use of figures: that they should be correctly used, and also that no attempt should be made to claim for them a greater precision than the subject admits of. The death-rate itself is acknowledged to be simply a convenient expression for something that gives a rough indication of the health of a district, and any figures arrived at from this basis by means of an approximate formula must be very wide of the mark. The true statement of the case is this. The reciprocal of its death-rate is roughly proportional to the state of health of a district, and is therefore roughly proportional to the duration of life in that district, generally speaking. The expression "mean duration of life" applied to any particular year is scientifically meaningless and misleading to the public.

I am, Sirs, yours faithfully,

Dec. 1889. T. GLOVER LYON, M.A., M.D. Cantab.

"BLINDNESS BY DISABILITY."

To the Editors of THE LANCET.

SIRS,—You will doubtless be deluged with letters on the subject of Dr. Gowers' communication in your last edition. Dr. Gowers, who is a consummate master of that most difficult instrument, the ophthalmoscope, warmly mentions a case of optic neuritis in chlorosis which, unfortunately, was under the care of a medical man unable to use the ophthalmoscope, and terminated ultimately in blindness. It was a sad case, certainly, and it would appear that the medical attendant was greatly to blame, not in my opinion so much on account of his ignorance of the ophthalmoscope as because he failed to properly treat the chlorosis, the cause of the neuritis, with its suitable and well-known remedy—viz., iron. All physicians and surgeons who specially study the eye and its diseases must every now and then come across the unhappy results of ignorance and incompetence, and I wonder what Dr. Gowers would say to the case of a poor fellow, only forty-seven, who came to see me a few weeks back, totally blind in his left eye, and with the following history. About two years ago he was admitted into a hospital suffering from some form of ulceration of the leg, and whilst in this institution an attack of typical acute glaucoma came on in his left eye, with severe pain and vomiting, and rapid loss of vision; no operation, he tells me, was ever suggested to him, the eye was treated with "lotion, drops, and caustic," and seven weeks from the onset of his attack he left the hospital with the sight of that eye completely gone, and when I saw him it was in a state of glaucoma absolutum, with the typical glaucoma cup, and to make matters worse, he is suffering from an old injury to his other eye, the sight of which is letters of 20 Jaeger slowly. In my innocence I had thought that every medical man knew of the existence of acute glaucoma, and that iridectomy, done in time, is an absolute specific for it. But Dr. Gowers refers to a wider subject—the instruction in the use of the ophthalmoscope given at the schools, and the number of the men who avail themselves of it. And here I think there is good cause for congratulation. I can myself speak for two schools. Eleven years ago I finished my hospital career in London, having, amongst other prizes, taken the medal for Practical Medicine, and I can safely say I never saw the optic disc all the time: indeed, the student who even possessed such a thing as an ophthalmoscope was a *rara avis*. It was not considered the thing to go into the Eye Department, and I never felt welcome there myself; one always seemed to be intruding, at least so I thought. Later I studied at Edinburgh University, and graduated there, dividing with another the prize given to the most distinguished graduate, and yet, I believe, only on one occasion had I succeeded in catching a hurried glimpse of the optic disc. I mention these facts, not in personal aggrandisement, to show that only a few years ago it was possible to take the highest prizes at two large schools of medicine without being able to recognise an optic disc; yes, or the vocal cords or membrana tympani either. I have fortunately been able to rectify those defects, and, returning and working at both my former places of study under a new *régime*, I am surprised to find the number of men with a very competent knowledge of the ocular fundus, and it would be impossible, I believe, now to take a prize for medicine at either institution without a good knowledge of the ophthalmoscope, and doubtless, ere very long, men will be unable to graduate at any university in the United Kingdom without being able to diagnose the various common diseases of the fundus of the eye. I am, Sirs, yours obediently,

S. JOHNSON TAYLOR, M.B., M.R.C.S.

Norwich, Nov. 25th, 1889.

THE MORTON LECTURE ON CANCER.

To the Editors of THE LANCET.

SIRS,—I am pleased to find that Dr. Inglis Parsons has reason to think that his operation may be effective at fewer sittings than I supposed, or even at a single sitting. I am quite satisfied that he has been before me in *publishing* the opinion that cancer cells escape the control of the nervous system, for I have never *published* any of my views on cancer; but that these latter are entirely independent, and, more than that, may turn out to be incorrect, is what I am equally ready to maintain. I will explain my views, and the processes by which I arrived at them, in a note to the Morton Lecture, when this is published.

I am, Sirs, yours truly,

Savile-row, W., Dec. 2nd, 1889. JOHN MARSHALL.

OPERATIVE TREATMENT OF FLAT-FOOT.

To the Editors of THE LANCET.

SIRS,—It has been strongly urged upon me that, if I still hold osteotomies for flat-foot to be unwarranted, because unnecessary, I ought not to allow Mr. Hare's paper in THE LANCET of Nov. 16th to pass unnoticed. But I have felt, as I did on reading Mr. Davy's communication to the Medical Society in March last, that if the facts and considerations which, during the past six years, I have repeatedly laid before your readers have not convinced, neither would anything for which I could reasonably ask you to spare me space be likely to do so now. Moreover, I have recently stated at full length, in a published book, my views on the physiology of the feet. Therein I have attempted to prove, among other propositions, these, which I first propounded more than sixteen years ago:—1. The muscles that *by* their action move the foot and the body upon it, *in* their action support the arch, which, in early life, they develop. 2. Flat-foot is due to failure of this functional support; renewal of functions in specially active manner will restore the arch. As, however, in my book I

Digitized by Google

have, as far as possible, avoided all surgical questions, and especially any which involve differences in opinion with eminent surgeons, I may ask permission to state here that I hold as strongly as ever the opinion that osteotomy for flat-foot is rarely, if ever, a justifiable operation, and certainly not in such a case as that described by Mr. Hare, which I do not regard as extreme.

I am, Sirs, yours faithfully,

Gloucester, Nov. 22nd, 1889. T. S. ELLIS.

AN EXPLANATION AND PROTEST.

To the Editors of THE LANCET.

SIRS,—As the editor of *Truth* has chosen to connect my name with what has been termed the "Clifton Scandal," I must ask you to allow me to state that my acquaintance with Mrs. Smith orginated in her bringing her daughter to me for a tumour of the jaw, upon which I operated last March in University College Hospital; that I allowed her to append my name to the perfectly unobjectionable prospectus of her school as a matter of charity, and only after making inquiry about her at Clifton; and that I entirely disapprove of her *modus operandi*, to which I never lent the least support, although my name, together with those of several highly respected clergy and doctors, was printed by *Truth* as if it had been appended to that disgusting document. I am, Sirs, yours obediently,

Cavendish-square, W., Dec. 3rd, 1889. CHRISTOPHER HEATH.

THE LATE GLASGOW UNIVERSITY GRADUATION CEREMONY.

To the Editors of THE LANCET.

SIRS,—In your last issue an account is given by a correspondent of a disturbance or riot which recently took place among our students, and I see that he repeats a fable current in the local prints that I had my gown torn off my back, while another medical journal adds that I was "roughly handled." Though there is not a shadow of foundation for these statements about myself, seeing I had no gown on and was subjected to no unbecoming treatment whatever, yet it is not to contradict such foolish assertions that I write, but because I feel that these accounts will be read with most painful surprise by our graduates, scattered all over the world, unless they are put at their true value. The whole affair has been most grossly and unfairly exaggerated in the local newspapers, and so far as I saw, the medical students, with a very few exceptions, had no hand or part in the business.—I am, Sirs, yours faithfully,

Glasgow, Dec. 3rd. GEO. H. B. MACLEOD.

COLOUR TESTS FOR RAILWAY SERVANTS.

To the Editors of THE LANCET.

SIRS,—The method illustrated in your issue of Nov. 23rd, p. 1056, in which Dr. Lediard employs coloured glass is undoubtedly very much better for railway purposes than the coloured wool test. However, an ordinary railway servant's hand-lamp, provided with red, green, yellow, blue, and purple glasses, would be far better than the appliance illustrated. Dr. Lediard appears to use his apparatus in a room; now that being so, the test is practically useless. A man may easily, for instance, see the red light in the doctor's room, but can he see the three or four red lights on the back of a train a mile in front of him?—that is the question. And, further, where there are extra lines of rails a man must be able to know how many red lights there are, and their positions.—I am, Sirs, yours truly,

CLEMENT E. STRETTON,
Consulting Engineer, Asso. Soc. Drivers and Firemen.

Saxe-Coburg-street, Leicester, Nov. 27th, 1889.

A DIET OF LEAN MEAT AND WATER.

To the Editors of THE LANCET.

SIRS,—I have been anxiously looking for some replies to the very interesting question raised by Dr. Herschell's paper in THE LANCET of Nov. 9th. I entirely agree with him that the time has arrived when our views as to animal diet should be reconsidered. For two years past I have been treating obese patients for limited periods on a diet mainly of lean meat and water, and I must emphatically say such a diet is well borne, and is greatly beneficial to the general health, especially in those cases previously suffering from dyspepsia, and the experience of over 200 cases leads me to think that the diet may be persisted in without any ill effects for long periods together. In most of my cases the average loss in weight was from 2 to 3 st. and 12 in. in abdominal girth. The stored carbon rapidly disappears. The Terra del Fuegans at Westminster, as Dr. Herschell urges, are good specimens of a diet almost entirely confined to lean horseflesh and water, and the all-important questions raised should be fully discussed. I agree with all Dr. Herschell puts forward, but wish to add my mite of experience gained in treating obesity by largely diluted animal food, in order to elicit from some of the well-known men who make dietetics a specialty their views on Dr. Herschell's carefully considered paper.

I am, Sirs, yours obediently,

Chancery-lane, W.C., Nov. 28th, 1889. W. TOWERS-SMITH.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

A Heavy Day at the Northern Hospital.

BETWEEN 7.39 A.M. and 5.9 P.M. on Monday, the 25th ult., the horse ambulance of the Northern Hospital was out twelve times. The following notes of the cases have been kindly forwarded by Mr. George M. Arkle, the ambulance surgeon. No. 1: W. C——, aged twenty-seven; fractured base of the skull; brought in dead. No. 2: E. F——, aged forty-two; concussion of the brain; admitted insensible. (Both these accidents were caused by falling down shipe' holds.) No. 3: J. W——, a male aged twenty; extensive scalp wound and slight concussion of brain, from a fall into a graving dock. No. 4: J. B——, aged fifty-one; two wounds of penis from being struck by a cart shaft, and shock. No. 5: S. S——, a boy aged fourteen; leg crushed between two bales of cotton; sprained ankle. No. 6: T. C——, male aged fifty-six; fracture of os calcis by fall from a scaffold. No. 7: B. M——, female aged sixty-six; bruised legs and side, sprained ankle, and shock, caused by being crushed beneath a falling bale of cotton. No. 8: B. S——, male aged thirty-two; immersion, cut on forehead, and bruised hip, caused by a fall into a dock while drunk. No. 9: J. H—— and W. T——, both males, aged thirty-eight and thirty; acute alcoholic poisoning. No. 10: R. D——, male aged twenty-three; compound fracture of arm, for which partial excision of the elbow-joint was subsequently performed. No. 11: E. S——, female aged twenty-four; extensive wound of forehead and nose, wound of hand, with much hæmorrhage. No. 12: W. S——, male aged twenty-eight; fractured ribs and severe shock from fall into a cellar. All the above were admitted as in-patients except No. 5 (made an out-patient) and No. 12, who went home against advice. On the evening of the same day an old man was admitted with strangulated inguinal hernia, and herniotomy was performed.

Bequests to Local Hospitals and Dispensaries.

The following bequests will be received from the executors of the late John Farnworth, a former mayor of Liverpool, who died in 1869, and whose widow has recently died:—£1000 each by the Lying-in Hospital and the Northern Hospital, and £500 each by the Royal Infirmary, and the North, South, and East Dispensaries.

Students' Dinner.

The annual dinner of the students of the Medical Faculty of University College took place at the Adelphi Hotel last Saturday. There were about ninety guests, the majority of whom were medical students. Professor Glynn presided, and Professor Rushton Parker responded for the professors.

Increased Prosperity and Intemperance.

In the annual report of the Head Constable for the year ending Sept. 29th last it is stated that "the number of cases of drunkenness has again risen—the usual, though lamentable, accompaniment of increased prosperity." This statement is abundantly confirmed by the number of cases brought before the magistrates on the last few Monday mornings, which has been increasingly more than for many years past. It is also clear that there are fewer unemployed labourers than there were some months ago. It is an unfortunate fact that drink appears to be obtainable

Digitized by Google

here even in bad times, much more so when they are prosperous; this is probably the case in other large centres of population, and Liverpool, while being no better, is probably not worse than London, Glasgow, or Bristol in this respect.

Liverpool, Dec. 3rd.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle.

THE Newcastle Saturday and Sunday Fund collections for the year have every appearance of presenting a very satisfactory improvement over those of 1888. From the published statements of the committee it is shown that the Church collections have been augmented by nearly £100, and the workmen's gathering by over £500, so that even so far there is an increase of £600 over last year. Much of the workmen's increase is due to the exertions of the honorary secretary of the fund, Mr. R. H. Holmes, who first, and after much labour, induced the adoption of the plan of a systematic collection in the factories of small weekly sums, and this mode of collection has fully justified his sanguine anticipations.—A very successful entertainment and conversazione was held last week in aid of our newest medical charity, the Cripples' Home at Wallsend. I am told that over 1000 tickets had been disposed of, and that the use of the hall was given free by Mr. James Deuchar. A very substantial sum is likely to accrue as a result to the charity.

Sunderland.

A very characteristic lecture under the auspices of the Sunderland Students' Society was given last week by the Rev. H. R. Haweis on Cremation.—At Dr. Collie's ambulance class for ladies at Bishopwearmouth, the Duncan Memorial fund was referred to, and it was stated that subscriptions had been received from all classes, ranging from £25 each, from Lord Londonderry and the Earl of Durham, to the shilling of the railway porter.

Durham: Rashness of Miners.

An inquest was held at the Durham County Hospital last week on the body of a miner who died in the institution from the effects of burns. It was shown that the deceased had set himself on fire by placing his pipe in the pocket of his coat, which presently burst into flames, inflicting such severe burns that Dr. Binnie of Brandon ordered his removal to the hospital. The coroner stated that he had known of similar cases before of fatal burns from lighted pipes; notably one where a miner put a lighted pipe into his pocket beside his powder flask, when an explosion took place and inflicted fatal burns about the chest and arms.

Middlesbrough.

It would appear from the statement made at the Board of Guardians that the decrease in pauperism is almost phenomenal. As compared with the corresponding fortnight of last year there is a decrease of 530 in the number of persons receiving out-door relief, and of £58 in the cost, altogether presenting good evidence of prosperous times.—Many will be sorry to hear that the experiment of placing Loch Leven trout in the Park lake at Middlesbrough has failed. About two years ago some 1500 yearling trout were placed in the lake, and to all appearance were thriving, but the conservator reported last week that they had been poisoned, probably from some contamination of the water by chemical refuse. Licences were about to be issued to anglers.

Newcastle-on-Tyne, Dec. 4th.

EDINBURGH.

(FROM OUR OWN CORRESPONDENT.)

The Edinburgh Health Society.

MR. SMITH CLARK, one of the members of a deputation from the Edinburgh Health Society to the Edinburgh Trades Council, was singularly happy in his choice of arguments in favour of a closer union between the Council and the Society. To no one is a clear understanding of the laws of health of greater importance than to the man who depends upon his bodily strength and the clearness of his head for his own maintenance and that of his family. It is one of the main objects of the Society to promote the advancement and well-being of the working classes generally, by any means which, from time to time, may be deemed advisable; and this deputation was sent to the Trades Council to ask them to interest the working classes still more in carrying out the objects of the Health Society by inducing them, their wives and their families, the various unions and other societies that are influenced by the Council's opinion, to come to the lectures that are given week by week, and also to become members of the Society. Last week the lecture was on Home Sick Nursing, by Miss Musgrove, Superintendent of the School of Cookery and Domestic Economy. It was full of sound advice and common sense, and was highly appreciated. The points on which special stress was laid were: as little furniture in a sick room as possible, good ventilation, supervision of visitors, good organisation, great self-control, and consideration for the patient. In the management of children, warm water and soap; regular, sufficient, but not excessive feeding; confinement to bed, and such-like matters, were insisted on. Other most practical advice as to the kind of bed, the administration of medicines, and the substitutes for poultices, was listened to with the greatest interest by a very large audience.

Extraordinary Graduation Ceremony.

At a meeting of the Senatus of the Edinburgh University, held last Saturday, the degrees of Bachelor of Medicine and Master in Surgery were conferred on forty-five candidates who had been unable to graduate at the August ceremonial. At the same time the degree of Bachelor of Science in the department of Public Health was conferred, after special examination, on nine graduates in medicine. It will be remembered that at the final examinations held last July a certain number of the candidates, who had failed in one subject only, were referred for three months, and were alowed to appear for re-examination in October. Of those so permitted to reappear forty-five were at this time successful in satisfying the examiners, with the result that they have not to spend another year in Edinburgh or some other medical school. Those who were rejected altogether have to take out two qualifying classes before they can again present themselves for examination. This new arrangement is a great boon to those who are just on the border line of the pass. It is certainly a great concession on the part of the University, and as such is highly appreciated.

New University Court Assessors.

At the meeting of the General Council of the University of Edinburgh held last week, Dr. John Duncan, Mr. McKie (Advocate), and Lord Kingsburgh were elected to act, along with Dr. P. H. Watson, as representatives of the Council on the newly constituted University Court. Of these gentlemen, Dr. Duncan and Mr. McKie are spoken of as advanced university reformers, whilst Lord Kingsburgh's accurate knowledge of the New Universities Bill and of the meaning read into the various clauses by the framers of the measure will be of great value to the Court. On Saturday the Senatus Academicus elected, as their additional representatives, Professor Taylor from the Faculty of Divinity, and Professors Sir William Turner and Crum Brown, both from the Faculty of Medicine. Professor Campbell Fraser, of the Faculty of Arts, is the other representative.

The Royal Society

At a general statutory meeting of the Royal Society, held last week, the following members of Council were elected:—President: Sir William Thomson. Vice-presidents: Professor Sir Douglas Maclagan, Hon. Lord M'Laren, Rev. Professor Flint, Professor Chrystal, Dr. Thomas Muir, and Sir Arthur Mitchell, K.C.B. General Secretary: Professor Tait. Secretaries to Ordinary Meetings: Professor Sir W. Turner and Professor Crum Brown. Treasurer: Mr. Adam Gillies Smith, C.A. Curator of Library and Museum: Dr. Alexander Buchan. Ordinary Members of Council: Dr. J. Batty Tuke, Professor Bower, Dr. G. Sims Woodhead, Mr. Robert Cox of Gorgie, Professor Isaac B. Balfour, Professor Ewing, Professor Jack, Professor Jas. Geikie, Mr. W. H. Perkin, jun., Mr. A. Beatson Bell, the Right Hon. Lord Kingsburgh, C.B., and Dr. John Murray. By a resolution of the Society the following hon. vice-presidents, having filled the office of presidents, are also members of Council:—His Grace the Duke of Argyll, K.G., K.T.; the Right Hon. Lord Moncreiff of Tulliebole.

Digitized by Google

Health Statistics.

In his return to the Public Health Committee for October, Dr. Littlejohn reports a death-rate of 16·36 per 1000 of population. Infectious diseases have been specially rife this year, as no fewer than 531 cases have been reported, and 34 deaths therefrom, of which 30 occurred in the Old Town. This number of intimations was twice as large as in any October for the last five years. Deaths from diseases of the chest numbered 99, from debility 34, measles 275, scarlatina 146, diphtheria 49, and typhoid fever 60. Dr. Russell, in presenting the report, pointed out that in the Old Town there were four times as many cases of infectious diseases as in the New Town, and, further, that the proportion of deaths was ten times as great in the Old Town as in the New—most important facts when taken in conjunction with the insanitary condition of the Old Town and St. Giles' Ward. During the month no less than 14,756 lb. of diseased or unsound meat have been confiscated—6839 lb. from the city and 7917 lb. from the country.

Edinburgh, Dec. 3rd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

DUBLIN.

Sir William Stokes, M.D.

AT a meeting of Convocation of the University of Oxford held last week, Sir William Stokes was selected as Examiner in Surgery to the University. This compliment to an Irish surgeon is one which cannot fail to be very gratifying to the profession in Ireland. Sir William Stokes is Professor of Surgery and Examiner in Surgery in the Royal College of Surgeons in Ireland.

Royal Medical Benevolent Fund Society of Ireland.

A quarterly meeting of the Central Committee was held at the College of Surgeons last week. Surgeon-Major J. B. Gaffney resigned the posts of honorary secretary and treasurer for the Bombay Branch, and Mr. Thomson also resigned similar offices for Dublin. In the room of the latter gentleman, Deputy Surgeon-General Henry King was appointed. Grants having been made amounting to £72 10*s.* to a few urgent cases, the proceedings terminated.

Rathmines Water-supply.

Professor Tichborne, who has recently examined this water, states that the suspended matter which can be seen in every sample is very objectionable. This suspended matter varies in quantity and quality with the locality. It is not all peat, but largely consists of alluvial sediment—earthy matter carried down by the streams,—some rich in oxide of iron from the pipes and peat. The removal of this suspended matter means much more than making it sightly water. Filtering means the removal of the earthy and unpleasant odour, and also the reduction of the organic nitrogenous matter, a fertile source of danger in summer. It also implies the production of a water-supply which would be constant in quality. Professor Tichborne urges that the filtering beds should be constructed before the summer months set in; and although the winter floods may probably make the supply unpleasant in character, this would be of small importance as compared with the changes which the tepid waters of July may bring about.

Death of Dr. Wm. R. McNab of Dublin.

This gentleman died suddenly on Tuesday morning from heart disease, aged forty-five years. On Saturday last he appeared to be in good health, and occupied the vice-chair at the annual dinner of the Scottish Benevolent Society of St. Andrew. He was Professor of Botany in the Royal College of Science, and was the author of several works on botany. He had a considerable knowledge of fossil plants and delivered numerous lectures on this subject. The deceased was a native of Scotland, but had been settled in Dublin for the past eighteen years.

Queen's College, Galway.

Dr. Augustus Dixon has been appointed Professor of Chemistry to this institution. Dr. Dixon studied under Professor Hoffmann of Berlin, and was afterwards assistant lecturer in chemistry to Dr. Reynolds, Professor of Chemistry, Trinity College, Dublin. The appointment is one which has met with universal approval.

Cork Union Workhouse.

An inspector of the Local Government Board—Colonel Spaight—has recently investigated the condition of this workhouse, and his report will come before the Cork guardians next Thursday. To relieve the present overcrowded state of the workhouse in an efficient manner, and yet at slight expense to the ratepayers, was the problem to be solved, and the suggestions of Colonel Spaight, it is believed, if carried out, will terminate the unsatisfactory and discreditable crowding on the male side of the workhouse and also in the female lunatic division.

Mr. David Turner has been elected resident medical officer to the Royal Hospital for Incurables.

Dublin, Dec. 3rd.

BELFAST.

University Extension Scheme in Belfast.

It has, I understand, been resolved to establish in Belfast a Society for the Extension of University Teaching, similar in its basis to other kindred associations in England and Scotland, and it is hoped that lectures on scientific and literary subjects will begin early next year. These will probably be delivered in Queen's College. The Mayor of Belfast (Mr. Connor, M.A.) and the President of Queen's College are taking a very active part in the movement, and a scheme has been drawn up giving details as to the management of the proposed new society. The lectures will be delivered in the evenings, and it is expected that they will be largely attended by young men who are engaged during the day in business pursuits.

The Royal Hospital.

The quarterly meeting was held on Nov. 25th, and the report read stated that during the past three months there were treated in the hospital 579 in-patients, and 238 medical and 341 surgical cases. During the same period there were 5643 extern cases. At the close of the financial year (Aug. 31st) the debt of the hospital was £1147 10*s.* 7*d.* The expenditure for the two months since then has been £1366 18*s.* 3*d.*, making a total of £2514 8*s.* 10*d.* The receipts for the two months have only been £517 15*s.* 9*d.*, so that on Oct. 31st the debt of the hospital was £1996 13*s.* 1*d.*, which is a very serious deficiency. For the post of resident surgeon there were two candidates—Dr. W. A. Wheeler and Dr. Gorman. The former, who received 88 votes to 24 for the latter, was elected. There is a strong feeling that it would be much better in these elections to appoint a small subcommittee, selected from the Board of Management and the medical staff, to be the body to elect the medical officers. At present it is necessary even for the post of house surgeon to canvass an electorate of more than three hundred persons.

The Belfast Charitable Society.

From the annual report read at the meeting of the friends of this—the oldest—Belfast charity I learn that with officers and servants there is a total of 179 persons at present in the house. The numbers seeking admission are far in excess of the accommodation in the house. During the past year, Dr. Esler (on going to London) resigned the position of assistant medical officer which he had held for several years, and Dr. Richard Purdon was appointed in his place.

Belfast Medical Students' Association.

The inaugural meeting of this Association was held last week at Queen's College. After a hearty vote of thanks had been given to Dr. O'Neill (the retiring President), Dr. MacKisack was elected in his place. Mr. Fullerton was appointed treasurer, and Mr. H. T. Heron, B.A., secretary.

Lisburn Union Workhouse.

At a meeting of the Lisburn Board of Guardians, held on Nov. 26th, Dr. M. B. Mackenzie was elected medical officer of the Lisburn Union Workhouse, in place of Mr. Samuel Musgrave, resigned. There were seven candidates.

Belfast, Dec. 3rd.

SCARCITY OF MEDICAL MEN IN AUSTRIA.—In consequence of the scarcity of medical men in some parts of Austria, an order has been issued by the Minister of Education that men recently qualified who have come from these localities must return to their homes to practise for a certain number of years unless they are fortunate enough to obtain some Government post elsewhere.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Paris Drinking-water.

THE defective supply of the drinking-water of Paris is still occupying the attention of the authorities. At a recent meeting of the Council of Hygiene, Drs. Chantemesse and Vidal observed that in the month of February, 1887, they had shown the intimate relation which existed between the increase of typhoid fever in Paris and the distribution of the water of the Seine. The researches and observations made since that period showed (1) that in 1889 the relations between these two factors were the same as those pointed out in 1887; (2) that the arrondissements provided with the Seine water had undergone a mortality from typhoid fever three or four times higher than that of the rest of the city, which was supplied with spring water. The practice here consists in distributing the water from the Seine successively to all the quarters, which proceeding is most favourable to the spread of typhoid fever.

Storing Food in Inhabited Rooms.

A writer in the *Gazette Médicale de l'Algérie* calls the attention of hygienists to the danger of eating butter impregnated with dangerous miasmata. Frequently the butter is prepared and kept in inhabited rooms, and sometimes even in rooms occupied by sick persons. Milk also is often kept in the same manner. The result is a contamination by morbific germs. Care should therefore be taken to obviate these grave risks to the public health.

Sugar in Urine.

Dr. Gaube, as the result of his observations, has arrived at the following conclusions, which he has published in the *Gazette Médicale de Paris*. The mean quantity of the normal sugar in the urine during infancy is 1 gramme per litre, 70 centigrammes in the adult, and 80 centigrammes at the age of maturity, per twenty-four hours. Every individual whose urine contains more than these quantities of sugar is, according to Dr. Gaube, in process of diabetic evolution, and the individual whose renal excretion contains less sugar is cachectic.

Myopia in French Schools.

Dr. Motais of Angers has made an interesting communication on the hygiene of vision amongst pupils in the schools and colleges of France. The author asserts that myopia in schools exists in France, as in Germany, in an alarming degree, and will increase if the authorities content themselves with simply formulating certain regulations without seeing that they are properly carried out. Dr. Motais has shown that myopia is not only a question of heredity or of race, but may be acquired, and it then often becomes hereditary. I need not here mention all the reforms advocated in his paper, as the greater part of them have already been pointed out by others who have studied this branch of hygiene. He, however, insists on the necessity of organising inspections in the schools. These inspections, besides being useful in preventing the development of ocular affections, would lead to the discovery of lesions which, taken in time, would be curable.

Pasteur Statistics.

According to the report published in the Annals of the Pasteur Institute, there have been treated at that institution from Nov. 1st, 1888, to Nov. 1st, 1889, 1830 persons bitten by rabid animals, of whom 11 have, in spite of the treatment, succumbed to hydrophobia. This gives a mortality of 0·60 per 100. Deducting, however, the number of persons (4) who died during the treatment or in the fifteen days which followed it, the mortality is reduced to 0·38 per cent., which figure is still inferior to that of the preceding years. It has been established that the number of deaths after treatment is becoming more and more reduced. For this year it is 1 per cent., whereas the mortality of cases not treated is less than equal to 15 per cent.

Paris, Dec. 3rd.

THE SANITARY INSTITUTE.—At the meeting on Dec. 11th, at 8 P.M., a paper will be read on "The Disposal of Sewage," by W. Santo Crimp, Assoc. M. Inst. C.E., F.G.S.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

"Antibakterikon."

A BERLIN chemical factory has produced a new kind of ozone water, which is said to be distinguished from other liquids of the kind by its freedom from lye of Javelle, and by its durability. It is to be patented under the name of "Antibakterikon," and is manufactured as follows:—Oxygen gas is made of chlorate of potassium and pyrolusite, and conducted into a pressure gasometer, whence it is sent through a series of so-called Siemens' tubes. With the help of a strong electric stream, produced by a machine similar to that which gives the electric light, a secondary stream is produced in these tubes, which discharges itself slowly but constantly, and converts the oxygen gas into an ozone solution of about 10 per cent. During this process various substances are added to the gas to prevent its evaporating. Dr. Otto Ringk of Berlin, the inventor of this new preparation, declares that it possesses extraordinary sanative virtues, not only producing a good effect in cases of tuberculosis, cholera nostras, typhus, diabetes mellitus, toothache, &c., but also destroying the virus of diphtheria and scarlet fever with absolute certainty. The future will show whether this news be not too good to be true.

The Tetanus Bacillus.

A Japanese physician named Kitasato has recently ascertained a series of important facts about traumatic tetanus in the Hygienic Institute of Berlin University, of which Robert Koch is the head. The first proof that traumatic tetanus is an infectious disease was given in 1884 by the Italian investigators Carle and Rattone, who inoculated rabbits with pus taken from a person suffering from this disease, and thereby produced fatal tetanus. A year later a student at Göttingen named Nicolaier, a pupil of Professor Flügge, made the highly important discovery that there are bacilli everywhere in the ground, which, if introduced under the skin of mice, guinea-pigs, and rabbits, invariably cause traumatic tetanus with fatal result. One year later the Göttingen surgeon Rosenbach showed that Nicolaier's tetanus bacilli are found, in persons attacked by traumatic tetanus, in the tissue where the infection began. It was therefore recognised that the bacillus discovered by Nicolaier is the cause of traumatic tetanus in human beings and animals. The exact study of these tetanus bacilli, however, was attended by many difficulties, chiefly because no one had succeeded in isolating them in pure cultivations, further cultivating them on an artificial nutritive basis, and finally producing tetanus experimentally with pure cultivations, all of which processes the rules of bacteriology require to be carried out with success before the theory of the tetanus bacilli can be regarded as proved even in its main points. Dr. Kitasato has now done this in a conclusive manner. He owes his success to the circumstance that he changed the usual method of cultivation. One of the chief difficulties was that, in order to thrive, the tetanus bacilli must be most rigorously guarded against the access of air. Dr. Kitasato's studies enable him to give a much more exact description of the tetanus bacilli and their way of life than has been given hitherto. In particular, he gives a precise account of the formation of spores. He also states that the destructive power of the tetanus bacillus is not in the least impaired by cultivation.

Professor Hans Virchow.

As already announced by us, Dr. Hans Virchow, a son of the famous pathologist, has been appointed Extraordinary Professor of Anatomy in the University of Berlin. He was born in 1852 at Würzburg, was educated in Berlin, and studied medicine, especially anatomy, in Berlin, Bonn, Strasburg, and Würzburg. His studies were interrupted by the French war, in which he fought for the fatherland as a lad of eighteen. He graduated in Berlin in 1875. His thesis for his degree was a report of a series of microscopic investigations of certain constituents of the ovum, and he chose microscopic anatomy as his special province. The narrower field of this wide province, to which he has devoted and still devotes special attention, is the finer structure of the eye. He has thoroughly studied its

Digitized by Google

details—the ramification of its vessels, the structure of the humour, &c.—in human beings and in animals. He published the results of these investigations in two essays, entitled, "On the Vessels of the Choroid of the Rabbit," and "Contributions to the Comparative Anatomy of the Eye." Another group of Dr. Hans Virchow's publications belongs to physiology, and relates to the motion and bearing of human beings. They are founded on very laborious observations of persons in action and in sleep, of acrobats, athletes, so-called caoutchouc men, and armless persons. He has taught in Berlin University as private lecturer and as demonstrator since 1884. Before that he was for about seven years assistant to Professor Kölliker of Würzburg. Berlin University now has two ordinary professors of anatomy, Waldeyer and Hertwig, and two extraordinary professors, Hartmann and Hans Virchow. Another of Rudolph Virchow's sons is a chemist, and at present assistant to Professor Liebreich; a third is a botanist.

Case of Blood-poisoning.

A somewhat singular case of blood-poisoning has occurred in Berlin. A woman walked across her room without slippers, and a pin ran into one of her feet. It was pulled out at once, but the foot soon swelled, with most violent pain, and a doctor was called in. He declared it to be a case of blood-poisoning caused by the circumstance that some of the coloured wool of the stocking had got into the puncture. He ordered her to be taken at once to a hospital, where the foot was amputated without delay. The operation was successfully performed, but the patient is not yet out of danger.

Cholera in Western Asia.

A Berlin paper hears from St. Petersburg that cholera is dying out in the provinces of Persia. In Southern Mesopotamia, on the other hand, all over Irak and among the nomads of the Syrian desert, who resist all medical superintendence, the epidemic is raging with great violence. The Persian authorities are executing the quarantine regulations with considerable rigour.

The Dengue Fever.

The dengue fever, the reappearance of which in the Piræus was announced a few days ago, forms the subject of an essay by Professor Zuelzer of Berlin, intended for von Ziemssen's special "Handbook of Pathology and Therapeutics." The first symptoms of the disease resemble those of apoplexy. As a rule, it keeps pretty well within the tropics, and is confined in Europe to the Mediterranean coasts and a part of Southern Spain. It is endemic on the coasts of the Red Sea. According to Vauvray, it breaks out every year at Port Said at the time of the date harvest, and is known there as the date fever. In the height of summer isolated cases have occurred in New York and Philadelphia.

A History of the Prussian Institutions for the Training of Army Surgeons.

Dr. von Coler, physician-general to the Prussian Army, has recently published an essay entitled "The Berlin Institutions for the Education of Army Physicians and Surgeons, their Origin and their Development." The first token of special care for the training of army surgeons in Prussia was the founding of the Theatrum anatomicum in 1713 by "the great drill-sergeant of Prussia," King Frederick William I. The idea was suggested to the King by Surgeon-General Hotzendorf. The next step in the same direction was the erection in 1724 of the Collegium medico-chirurgicum, which was open to all students of medicine, but accorded certain privileges to those who intended to enter the army. The famous Pepinière, an institution intended simply and solely for the training of physicians and surgeons for the army, was founded in 1795; it was the good result of the very sad experience of the Prussian army in respect to the care of the sick and wounded in the wars of Frederick the Great.

Berlin, Nov. 26th.

THE CHURCH OF ENGLAND FUNERAL REFORM ASSOCIATION has lately, through its hon. sec., the Vicar of Westow, York, issued a manifesto in which it complains of lack of funds. The objects of the Society—namely, the minimising of the expense of funerals, and securing throughout the kingdom the use of coffins of a readily-perishable material—are such as ought to commend themselves to the public.

Obituary.

RICHARD VON VOLKMANN.

RICHARD VON VOLKMANN, one of the greatest of German surgeons, died at Jena on Nov. 28th. He was born at Leipsic on Aug. 17th, 1830. His father, Alfred Wilhelm Volkmann, was a famous physiologist, and held the chair of physiology in the University of Halle from 1843 till 1877. Richard Volkmann studied at Halle, Giessen, and Berlin. He established himself as a private lecturer in Halle University in 1857, and was appointed ordinary professor of surgery and head of the surgical hospital there in 1867. He was with the Prussian army in the wars of 1866 and 1870–71, in the latter of which he accompanied the fourth army corps as surgeon-general. He has always stood true to the University of Halle, which loses its brightest ornament in him. When Langenbeck retired to well-earned repose in 1882, the professorship of surgery in Berlin was offered to Volkmann and declined by him. He was a kind of king in Halle. One of his chief merits, probably the greatest of all, was that he was one of the first and most enthusiastic apostles of Lister's method in Germany. He simplified Lister's bandage, showed the application of crimped gauze, introduced chloride of zinc as an antiseptic, created the conception of "aseptic wound-fever," and did all that in him lay to get Lister's method introduced without delay in hospitals and in private practice all over Germany. But it was not only as the eloquent advocate and active propagator of Lister's great reform (which, owing to the less scrupulous cleanliness of German hospitals, was still more salutary in Germany than in Great Britain) that Volkmann gained an undying name; his treatment of diseases of the joints, especially in children, of wound-erysipelas, lupus, and synovitis, and his investigations of the growth, bending, and atrophy of bones and of tumours, especially cancer-tumours, among paraffin workers, entitle him to rank among the great benefactors of mankind. He was at the same time one of the best teachers of surgery, and his lectures on diseases of the joints are regarded as the best treatment of the subject in existence. His name also stands high in the imaginative literature of Germany, and he will long be remembered in non-scientific circles as the author of "Reveries at French Firesides." These poetical effusions were written in the intervals of his hard surgical work in the Franco-German war, and were originally intended for his own children, but have gone through fourteen editions and become the common property of the German nation. He had suffered for several years from a severe affection of the spinal cord. A long stay on the Lake of Constance and journeys in Italy so far restored him that he was able to resume his work in Halle last summer. His work, however, soon proved too much for him, and he had to give it up entirely. Severe neuralgic pains induced him to consult Professor Binswanger of Jena some weeks ago. He had invited the chief German surgeons to meet him in Halle on Nov. 17th to constitute the surgical section for the International Medical Congress that is to meet in Berlin next summer. Notwithstanding the delicate state of his health, he kept this appointment, and took part in the deliberations with his wonted vivacity. On his return to Jena he was prostrated by inflammation of the lungs, and paralysis of the heart suddenly ended his sufferings.

THE SERVICES.

ARMY MEDICAL STAFF.—Deputy Surgeon-General Wm. Cattell has been placed on retired pay (dated Nov. 23rd, 1889).—The undermentioned Surgeons-Major to be Brigade Surgeons, ranking as Lieutenant-Colonels:—Wm. Winslow Tomlinson, vice J. Robinson, retired (dated Nov. 4th, 1889); William Sparks Martin Price, vice W. Temple, V.C., M.B., retired (dated Nov. 7th, 1889).

Surgeon Justin F. Donovan, M.D., has been allowed to withdraw, with a gratuity, from the Service, which he entered in March, 1879. In 1882, while Surgeon of Jamaica Hospital, he received the expression of their lordships' great satisfaction at the display of zeal and devotion to duty manifested during the epidemic of yellow fever at

Digitized by Google

Jamaica; and in 1888 a like expression for the manner in which his duties were performed during his three years' commission at Malta Hospital. Dr. Donovan has been appointed to an important position in the Colonial Medical Service at the West Indies.

ADMIRALTY. — The following appointments have been made:—Surgeon Robert H. Nicholson to the *Swallow*, and Surgeon William H. O'Meara to the *Hercules* (both dated Nov. 29th, 1889); Staff Surgeon Robert Bentham to the *Cordelia*, Staff Surgeon Charles James to the *Caroline*, Staff Surgeon John A. M'Adam to the *Neptune*, Surgeon William Hayes to the *Cordelia*, Surgeon Bassett C. E. F. Gunn to the *Alacrity*, and Surgeon Johnston H. Acheson to the *Rattlesnake* (all dated Dec. 6th, 1889).

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—In consequence of arrangements for alterations to the electric light apparatus, the library of the College will be closed on Tuesday next, the 10th inst., at 3 P.M.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—Mr. James Harry Poland, M.R.C.S. and L.S.A. Lond., Surgeon Superintendent, Queensland Emigration Service, having passed the necessary examination, has been granted the Diploma in Public Health of the College.

FOOTBALL CASUALTY.—During a football match on Saturday last, at Shipley, near Bradford, between Shipley and Manningham Rangers Club, George Flaxington, a Shipley forward, sustained a fracture of the leg below the knee.

NOTTS COUNTY ASYLUM.—At the last meeting of the County Lunatic Asylum Committee of the Notts County Council, an important report was received from the Commissioners in Lunacy, in which the County Council are recommended to build a new County Lunatic Asylum.

SANITATION OF CAIRO.—Mr. Latham, the sanitary engineer specially commissioned to report on the measures necessary to improve the sanitary condition of Cairo, is stated to have recommended 240 miles of sewers and a system costing about half a million sterling.

BEQUESTS.—Mrs. Margaret Baxter has left £100 to St. Joseph's Asylum and £100 to the Royal Hospital for Incurables.—Miss Harriet Saurin has bequeathed £600 to the Convalescent Home, Stillorgan, £250 to the Adelaide Hospital, and £250 to St. Patrick's Home for Nurses for the Sick Poor.

THE HONG-KONG SANITARY BOARD, only recently constituted, with the Colonial Surgeon and the Captain Superintendent of Police as president and vice-president respectively, does not appear to have been of much public utility. The office of coroner has been abolished, and the duties have been transferred to the police magistrates.

ROYAL HULL INFIRMARY.—ON Tuesday, Nov. 19th, a most enjoyable concert was organised by Staff Surgeon Alfred Corrie, R.N., for the amusement of the inmates of the Royal Hull Infirmary. A striking feature of the entertainment was that it was purely naval, all taking part in it belonging in some way or other to the navy. At the end of the entertainment the senior consulting surgeon of the institution, Dr. Lunn, proposed a hearty vote of thanks to Staff Surgeon Corrie and those taking part in the concert.

THE PINE TREATMENT OF DISEASE.—A number of representatives of the medical and scientific press assembled by invitation last Tuesday at the Hydro-Therapeutic Institution at Farnborough, on the occasion of the anniversary of the establishment being opened. It is claimed for this institution, the medical officer of which is Dr. Vaudrey, that the system of baths and massage can here be obtained in their entirety, and during the past year many patients have been sent there by their medical advisers. At the banquet in the evening, the chairman, Mr. Nethersole, gave an encouraging report of the progress made, and announced that a new wing would have to be erected for the reception and treatment of patients unable to pay the full fees. Congratulatory speeches followed, and after an enjoyable evening the guests returned to town in a special train courteously provided by the management.

LECTURES AND DEMONSTRATIONS ON OPHTHALMOLOGY.—A useful series of lectures and clinical demonstrations are now in progress in the Newcastle Infirmary for Diseases of the Eye, conducted by Mr. C. S. Jeaffreson. The first lecture, which was delivered on Nov. 9th, was on the Relation between Ophthalmology and General Medicine and Surgery. Dr. Benjamin Barkus occupied the chair, and numerous lantern slides of various diseases of the tendons were exhibited and explained, there being about fifty medical men and students present. The first clinical demonstration took place on Friday evening, Nov. 29th, when many interesting cases were exhibited and explained. The dates of the lectures and demonstrations are given in our advertising columns.

FATAL DISPENSING BY A GERMAN CHEMIST'S ASSISTANT.—A chemist's assistant in Magdeburg has been sentenced to a year's imprisonment for dispensing a morphia ointment instead of a calomel powder for a child, thereby causing its death. The assistant's principal was at the same time sentenced to three months' imprisonment.

A NEW EYE INSTITUTION FOR CHESHIRE.—At the final public meeting held at Altrincham, on Thursday, Nov. 28th, it was unanimously decided that an eye hospital, bearing the title of the Altrincham and District Eye Institution, be opened. The institution is intended to cover the wide area and large population known as Mid-Cheshire. At present no beds will be attached, there being an excellent small general hospital in the town available under certain restrictions. Dr. P. H. Mules, late surgeon to the Manchester Royal Eye Hospital, has been elected medical officer.

HOSPITAL SATURDAY COLLECTIONS, LINCOLNSHIRE.—On Saturday, a well-attended public meeting was held at Gainsborough, to hand over the amount of the Hospital Saturday collection to Canon Hutton, on behalf of the Hospital Board. Mr. James Marshall presided. The Gainsborough Committee had collected £148 14*s.* 7*d.*, which would be divided between the Lincoln County Hospital and the Leeds Eye and Ear Infirmary. The Sleaford total was £125, and Lincoln £320 18*s.* Since the commencement of this movement in 1879 the hospital authorities have received by it a total of £5504.

LITERARY INTELLIGENCE.—From a circular that has reached us, it would appear that von Ziemssen's "Handbook of General Therapeutics" is to be issued to the profession by an American firm at a discount of a little over 22½ per cent. from the English price. This edition is not a new translation, but, so far as can be judged from the circular, it is a reprint of the edition in seven volumes issued by Messrs. Smith, Elder, and Co.——We understand that an American edition of the *Nursing Record*, in addition to the ordinary issue, has been commenced, and will be published weekly in New York.

THE HOUSING OF THE POOR.—At the usual meeting of the London County Council this week, the Housing of the Working Classes Committee reported that they had before them the subject of the arrangements which should be made in any buildings which might be erected under the control of the Council for the housing of the poorer classes, particularly as regards the staircases, basement floors, bath-rooms and closets, and the size of the rooms. The committee had repeatedly considered these questions in conference with the medical officer and the architect, and they now submitted suggestions as to all these matters, which were approved and adopted by the Council.

GLASGOW WESTERN INFIRMARY.—At the fifteenth annual general meeting of qualified contributors to this institution held in Glasgow last week, the report, which was adopted, showed that the ordinary income amounted to £15,874 10*s.* 2*d.*, and the ordinary expenditure to £18,951 3*s.* 10*d.*, showing a deficit of £3076 13*s.* 8*d.*, against a deficit in the previous year of £3515 9*s.* 9*d.* It was gratifying to the managers to observe that there was an increase in almost every branch of the ordinary income during the past year. The managers still heartily commend to the working classes generally the systematic method of making their contributions now in force in most of the large public works and ship-yards in and around Glasgow. Several speakers urged the importance of a convalescent home being established in connexion with the infirmary, and attention was called to the value of the infirmary as a medical school.

Digitized by Google

THE BRADFORD INFIRMARY.—On the 15th inst. a meeting of the Board and Visiting Committee was held in the Board-room, for the purpose of considering what further steps should be taken to secure a large addition to the annual subscription list, and also with a view of obtaining donations towards the liquidation of the debt of £2000, incurred by the opening of the new wing to the infirmary in 1885. The Mayor (Alderman S. Feather) presided. After considerable discussion it was resolved unanimously that further efforts should be made in continuance of the work initiated by the Board, and that the Finance Committee be requested to prepare a scheme for a thorough canvass of the town.

PRIZES OF THE SPANISH MEDICO-CHIRURGICAL ACADEMY.—The Spanish Medico-Chirurgical Academy has just announced the subjects for the prizes to be awarded next year. The competition is open to all nationalities, and the essays may be written in English. They must not be signed, but marked with a motto and accompanied by a sealed envelope containing the name and address of the writer, and bearing on the outside the same motto as the essay itself. They must be addressed to the President of the Academy, and must be forwarded to the Secretary, Montero, 22, bajo, Madrid, before Sept. 15th, 1890. The first prize, which is offered by the Academy itself, consists of 250 francs and the title of Corresponding Fellow. The subject is "Have the Modern Discoveries of Physics applied to Medicine advanced the Science of Diagnosis?" The second prize, that of Don Antonio Espina y Capa, consists also of 250 francs and the title of Corresponding Fellow. The subject is "The Limits of Expectancy and the Therapeutic Value of Hygiene in Chronic Diseases of the Stomach."

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BAILDON, FRANCIS J., M.B., C.M., has been appointed Honorary Medical Officer to the Southport Infirmary, vice Dr. A. Jones, resigned.

BEVAN, RICHARD, D.P.H. & L.R.C.P. Lond., M.R.C.S., L.S.A., has been appointed Medical Officer of Health to the Borough of New Romney, Kent.

BOOTH, F., M.B., C.M. Aber., has been appointed Medical Officer of Health of St. Anns-on-the-Sea, Lanc.

CAREY, BASIL DE B., M.A., M.B.Cantab., M.R.C.S., L.S.A., has been appointed Surgeon to the Hospital and Parish of St. Peter Port, Guernsey.

CHEPMELL, CHARLES W. T., M.D. Brux., M.R.C.S., L.R.C.P. & S. Ed., L.F.P.S. Glas., has been appointed Surgeon to the London, Brighton, and South Coast Railway Provident Society.

GIRLING, CHARLES J., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant House Surgeon to the Halifax Infirmary and Dispensary, vice Andrew Robertson, M.A., M.B., C.M. Edin., resigned.

HARRISON, A. J., M.R.C.S., L.S.A., has been reappointed Physician to the Bristol General Hospital.

HAWKINS, W. R. T., M.R.C.S., L.S.A., has been reappointed Medical Officer, Second District, Barton Regis Union.

LOCKWOOD, W., M.B., C.M. Edin., has been appointed House Surgeon to the West Bromwich District Hospital.

LOWNDS, J. R., M.R.C.S., L.S.A., has been appointed Medical Officer of the Green Hammerton District, Great Ouseburn Union.

LYNCH, G. W A., B.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed a District Medical Officer in Fiji.

MACDONALD, J. A., M.D., M.Ch., B.A.O., Roy. Univ. Irel., has been appointed Honorary Physician to the Taunton and Somerset Hospital, vice Dr. Alford, resigned.

MACKENZIE, M. S., M.D. Irel., L.R.C.S. Edin., has been appointed Medical Officer, Lisburn Dispensary District.

POWERS, C. H., L.R.C.P., M.R.C.S., has been appointed Clinical Assistant to the Metropolitan Asylums Board, South-Western Fever Hospital, Stockwell, S.W.

PRATT, A. A., M.B., C.M. Glas., has been appointed Assistant House Surgeon to the West Bromwich District Hospital.

PURVES, A. S., M.D. Edin., has been appointed Medical Officer of the Lesbury District, Alnwick Union.

SADLER, M. T., M.D. Lond., M.R.C.S., has been reappointed Medical Officer, Worsborough.

SHARPE, J. H., M.D. Irel., has been appointed Medical Officer of the Huntspill District, Bridgwater Union.

SHIVES, JOHN, M.D. Aber., L.R.C.S. Edin., has been reappointed Medical Officer, Liversedge Union District.

SMITH, TELFORD, B.A., M.D., B.Ch. Univ. Dub., has been appointed Assistant Resident Medical Officer to the Royal Albert Asylum for Idiots and Imbeciles of the Northern Counties, Lancaster, vice F. W. Nielsen, M.A. Cantab., M.R.C.S., &c., resigned.

WHEELER, T. K., M.D. Irel., has been appointed Resident Surgeon to the Belfast Royal Hospital.

WOODYATT, J. F., M.R.C.S., L.R.C.P. Lond., has been appointed Senior House Surgeon to the Halifax Infirmary and Dispensary, vice W. W. Chamberlain, M.B., C.M. Edin., resigned.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

BLACKBURN AND EAST LANCASHIRE INFIRMARY, Blackburn.—Junior House Surgeon. Salary £50 per annum, with board, washing, and lodging.

DISPENSARY, Worksop.—Resident Surgeon. Salary £120 per annum, with rooms, coals, gas, furniture, and housekeeper found.

DONCASTER GENERAL INFIRMARY AND DISPENSARY.—House Surgeon. Salary £100 per annum, with board and residence in the house.

Medical Diary for the ensuing Week.

Monday, December 9.

CHARING-CROSS HOSPITAL.—Operations, 3 P.M.
ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, daily at 10 A.M.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.
ST. MARK'S HOSPITAL.—Operations, 2.30 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.
UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.
SOCIETY OF ARTS.—8 P.M. Mr. William Jago: Modern Developments of Bread Making. (Cantor Lecture.)
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Douglas Powell will open a Discussion on the Diagnosis and Treatment of Aneurysm of the Aorta.

Tuesday, December 10.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays at the same hour.
GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electro-therapeutics, same days, 2 P.M.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. Arthur E. Nevins: On the Frequent Association of Heart Disease, especially Mitral Stenosis, with Diseases of the Pelvic Viscera, in Women.—Mr. Ed. Roughton: On Blood Tumours (angeiomata and angeiosarcomata) of Bone.

Wednesday, December 11.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M. Operations by the Obstetric Physicians on Thursdays at 2 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M. Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M.; Surgical Visits on Wednesday and Saturday at 9.15 A.M.
HUNTERIAN SOCIETY.—8 P.M. Pathological Evening. Dr. Fowler: Papillomatous Growth of Uvula.—Mr. Rivington: (1) Sarcoma of Foot; (2) Exostosis.—Mr. Openshaw: Malformed Uterus.—Dr. Davies: (1) Sarcoma of Lung; (2) Sarcoma of Kidney.—Mr. Bidwell: (1) Acute Necrosis of the Atlas; (2) Abscess of Sternum and Liver from a case of Pyæmia.—Mr. Poland: Carcinoma of the Sigmoid Flexure.
ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. A. W. Bennett: On the Freshwater Algæ and Schizophyceæ of Hampshire and Devon.
SOCIETY OF ARTS.—8 P.M. Mr. H. Trueman Wood: The Paris Exhibiton.
BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Council Meeting at 8 P.M. Discussion on Mr. Lawson Tait's paper on "A Reply to some recent Observations on Ectopic Gestation."—Dr. Benington: A Case of Lunacy Cured by the Use of a Pessary.—Mr. Bowreman Jessett: The Surgical Treatment of Cancer of the Uterus. Specimens will be shown.

Thursday, December 12.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.
CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, VICTORIA-PARK, E.—4.30 P.M. Dr. Clifford Beale: On Laryngeal Affections in Phthisical Persons.
OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8.30 P.M. Patients and Card Specimens at 8 P.M. Mr. Treacher Collins: Microscopical Sections of Lens with Epithelium on the Inner Surface of the Capsule, and showing other peculiar Structural Changes.—Mr. Jessop: (1) Aniridia, with Dislocation of Lens; (2) Punctate appearance of Anterior Capsule of Lens; (3) Vacuoles in Lens.—Mr. Tatham Thompson: Note on a case of Hereditary Tendency to Cataract in Early Childhood.—Mr. Tweedy: On the Operative Treatment (1) of Cicatricial Ectropion of the Lower Lid; (2) of Symblepharon.—Mr. Hill Griffith: A case of Primary Tuberculosis of the Iris.—Mr. C. Wray (introduced): On a form of Conjunctivitis.—Mr. Spencer Watson: Osteoma of the Infra-superciliary Region.

Friday, December 13.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
CLINICAL SOCIETY OF LONDON (at 20, Hanover-square).—Living Specimens at 8 P.M. Papers at 9 P.M.:—Mr. C. Symonds: Nine cases of Thyroid Cysts and Adenomata treated by Excision.—Mr. W. H. Battle: Case in which a Diffuse Aneurysm developed in the Calf of the Leg, simulating Abscess; recovery after removal of parts of the popliteal and tibial arteries.—Mr. W. G. Spencer: Case of Traumatic Aneurysm following a Fracture, dislocation of the spine in the dorso-lumbar region, and presumably connected with the lumbar arteries.

Saturday, December 14.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE ST. ANDREWS M.D.

Mr. G. L. Hill.—The degree of Doctor of Medicine of the University of St. Andrews has never been obtainable without examination during the last fifty years at least. In the old times, in company with other universities, St. Andrews did now and then confer the medical degree "on recommendation," as the Lambeth degree is still conferred; but as far back as the date when Dr. John Reid, who died about forty years ago, was Chandos Professor of Medicine in the University medical degrees have never been conferred except after examination—a change which Dr. Reid did not originate, but which he very greatly improved. Under Dr. George Day, who succeeded Dr. Reid in the Chandos Professorship, the examination became more stringent, was made both written and oral, extending over three days, and was in every particular brought up to the same character as that for membership of the London Royal College of Physicians.

C. O. H.—Our correspondent will see, by reference to our report of the proceedings of the General Medical Council, that in future there will be appended to the foot of every licence dated on or after June 30th, 1887, an intimation that the holder is legally qualified for the practice of medicine, surgery, and midwifery.

T. F. M.—The manufacturers are Messrs. Farrow and Jackson, 8, Haymarket, London, S.W. A description of the process will be found in THE LANCET of Nov. 2nd, 1889, page 925, in an article entitled "The Brewers' Exhibition."

Q. E. D. could hardly do better than consult Dr. McVail's work, "Vaccination Vindicated," published by Cassell and Co.

T. G. H.—Our remarks at the foot of a letter signed "Veritas," on p. 1146, will answer the queries of our correspondent.

THE PREVENTION OF EPIDEMIC DISEASE.

To the Editors of THE LANCET.

SIRS,—As milk has been incontestably shown to be the chief, if not the only, article of food capable of producing outbreaks of epidemic disease, I would suggest that every dairyman should be compelled to notify to the medical officer of health of the district the sources whence he obtains his supplies, and that every householder, or his representative, who notifies as to the existence of infectious disease in his dwelling should state the name and address of the dairyman whom the person affected has employed. By such means the medical officer of health would readily be able to see how far and what supply was likely to be the cause of any epidemic outbreak; and he could also at once, on suspicion, examine the sources from which the milk was originally drawn, as well as the dairy that retailed it.

I am, Sirs, your obedient servant,

Surbiton, November, 1889. F. P. ATKINSON, M.D.

THE ABUSE OF HOSPITALS.

Mr. John Weaver (Southport).—We regret exceedingly to be unable to insert our correspondent's letter, but its length precludes the possibility. We give the pith of Mr. Weaver's views, based on an intimate and prolonged study of the working of two provincial hospitals. He thinks the abuse of hospitals by in-patients—in the provinces, at least—to be very slight. He is convinced on this point. In the out-patient department it is very different. Here there is extensive abuse. First, in the way of minor accidents—a source of abuse much overlooked, and of which he has seen hundreds of cases that could quite well have paid a practitioner for attendance. Secondly, by out-patients who can well afford to pay. This form of abuse is growing rapidly, on account of the increasing faith in hospitals. There are few men who, thinking they can benefit the health of their child, for instance, by getting gratuitous medical advice at a hospital, will hesitate as to whether or not they ought to do so. Thirdly, by patients who from their extreme poverty should be on the parish. The majority of these prefer to go to the hospital. The voluntary hospital and the parish medical department compete, and the charitable public pay twice over. Further, home visiting by hospital officials is doing the work of the Poor-law medical officers. As to remedies. The minor accident cases should be investigated after the Manchester Infirmary system, and payment insisted on where abuse is found. In the case of other patients who can afford to pay, they should be prevented from going to the hospitals. In one hospital known to our correspondent a subcommittee sits before the medical officers attend to examine into the fitness of cases. He thinks the working classes resent this mode of inquiry less than that by a paid agent. As to hospital attendance on the pauper classes, the only remedy Mr. Weaver suggests is that of greatly improving the attention they at present receive from the parish, and determining how far down in the social scale the voluntary hospital system should go.

Mr. W. Moore (Stourport) urges that the evil done to the profession by abuse of hospitals is not so great as that done by medical aid associations, which attract highly paid artisans, publicans, tradespeople, farmers, and other persons who hitherto have been in the habit of paying for the medical attendance of private practitioners. Our correspondent seems to have suddenly made this discovery, and not to be aware that it has been shown for years by ourselves and others as a most obvious evil. He points out that such associations generally appoint a young man, a stranger in the neighbourhood, and lower the conception of the value of medical service in the whole neighbourhood. Medical men themselves have to bow to the generally lowered estimate of their work, and cater accordingly. He thinks the only remedy is a combination of the whole profession. Dr. Rentoul should, he suggests, devote his attention more to this aspect of the question, and endeavour to organise the profession to a great combined protest against the evil. He promises soon to send a few *practical* suggestions. If they are really practical, and reach us in a succinct form, we shall try to give them insertion.

ETHER, CHLOROFORM, NITROUS OXIDE GAS AND ETHER.

To the Editors of THE LANCET.

SIRS,—It is not my intention to open up the vexed question of the comparative safety or otherwise of these drugs as anæsthetics, but merely to give my own personal experience of them. On six different occasions within the past ten years I have unfortunately required the administration of one or other of them. My initial experience was with ether, which was given me in a towel formed into a cone with a sponge at the top. After getting over the choking in the first, and on passing into the second, stage I became so violently delirious that it required the utmost efforts of three strong men to restrain me. I may say that I am a powerful man, and was at the time in training for boxing. The after effects—sickness, nausea, and general misery—I did not get over for quite forty-eight hours. My next experience was with chloroform, which I have had in all four times. It was administered on each occasion through a Junker's inhaler. I quickly went under, and as quickly came to; but the nausea, which lasted from thirty-six to forty-eight hours, was very trying, and exhausted me a good deal. Quite recently I have had to seek the services of a surgeon at another hospital; and, when informed in the theatre that it was intended to give me ether, I must say that I dreaded the anæsthetic much more than the surgeon's knife. I was first given nitrous oxide gas to produce insensibility, and then ether was substituted. Altogether I was twenty minutes inhaling the latter. Within a few minutes of removing the ether I was able to answer questions, although I did not fully recover consciousness until removed to my ward, and within an hour I was entirely free from all unpleasant effects of the anæsthetic, and able to partake freely of bread and milk. I may add that on each occasion I was prepared *secundum artem* for the reception of the drug, and the time of inhaling lasted about the same—viz., twenty minutes. Such, shortly, has been my experience, and I need hardly say that I much prefer Mr. Braine's combination of nitrous oxide and ether.—I am, Sirs, yours truly,

Nov. 30th, 1889. F.R.C.S.

THE MEDICAL WORK OF FRIENDLY SOCIETIES.

THE following account, from the *Bournemouth Gazette* of Nov. 9th, of his stewardship by the medical officer of the Poole Friendly Societies' Medical Association is a striking illustration of the way in which one man is made to do the work of three in this arrangement:—

"The Surgery, Mount-street, Poole, Oct. 10th, 1889.—To the Chairman and Members of the Committee of the P.F.S.M.A.—Gentlemen, I have great pleasure in presenting to you my third quarterly report. As I have never been absent from the surgery on a single day during the three months, but have always had the surgery open night and morning, the figures as under represent a correct index of work done:—Prescriptions dispensed, 3638; visits at patients' homes, 776; teeth extracted, 143; candidates examined for membership of various friendly societies, 58; midwifery cases attended, 31; deaths, 10; operations and appliances, 15; vaccinations, 11—total, 4682. The above gives a daily average of nearly 51. The hardest day's work was on the last day of the quarter (Sept. 30th), when 118 was the total. [In one day, 118 patients seen!] Excluding Sundays, the lightest day's work was on Aug. 5th, with a total of 29. During the last five weeks of the quarter the work was unusually heavy, one week alone having a daily average of nearly 72.—I have the honour to remain, yours obediently, W. T. GARDNER ROBINSON, M.D., Medical Officer."

The total receipts of the management account for the three quarters were £433 4*s.* 6*d.*, which included contributions from friendly societies, clubs, and public members, entrance fees, accouchement and vaccination fees, and surgical goods sold to members. The total expenditure was £376 15*s.* 11*d.*, which included salaries of *locum tenens*, drugs, preliminary expenses, working expenses, rates, interest, and insurance, the result being a balance—net profit—of £56 8*s.* 7*d.* on the three quarters. The Association has now 3136 members—1851 from various friendly societies and clubs, and 1285 public members. They have secured the services during the winter months of an M.D. to assist the medical officer, and they also employ a dispenser. Well might a vote of thanks be passed to the auditors and the hon. secretary. We do not read of a similar compliment to the medical officer. He was a *paid* servant.

Mr. Endean (Locarno).—The MS. has been received, and is receiving attention.

BRITISH MEDICAL BENEVOLENT FUND.

To the Editors of THE LANCET.

SIRS,—The advent of this spell of cold weather is bringing me numerous letters begging for warm clothing for women and children, and, alas! my chest is empty. I should be truly obliged if some readers of THE LANCET would send me, as soon as they can conveniently overhaul their stores, such articles of underclothing or warm jackets and cloaks, or wraps of any sort that they think would be useful. This does not mean that I do not want men's clothing; on the contrary, everything with any wear still in it is most welcome and useful.

Will you kindly give this room in your next issue, and oblige,

Yours very truly,

EDWARD EAST, Hon. Sec.

16, Upper Berkeley-street, Portman-square, W., Dec. 2nd, 1889.

AMMONIA IN COCAINE POISONING.

To the Editors of THE LANCET.

SIRS,—In last week's issue of THE LANCET Dr. Golovkoff is reported to have said that the only case in medical literature where ammonia was used as an antidote in cocaine poisoning was one by Dr. Goodlad, reported in THE LANCET of 1888, vol. i., p. 394. If he refers to the second volume of the same year, p. 715, he will find another case, in which the symptoms were similar to those described by him. In this case I freely administered the aromatic spirit of ammonia, and the patient quickly recovered and was able to go home in half an hour after the onset of the symptoms. Here seven minims of a 20 per cent. solution were injected. I am, Sirs, yours faithfully,

Stamford-hill, N. DANIEL MOWAT, M.D.Edin.

THE USE OF THE OPHTHALMOSCOPE.

To the Editors of THE LANCET.

SIRS,—In answer to Dr. W. R. Gowers' letter, published in your issue of Nov. 23rd, p. 1083, wherein he asks, "Has any student ever yet been definitely tested in the use of the ophthalmoscope in the pass examination for a diploma?" I should be glad for him to know that when "up" for my L.S.A.Lond. I was given more than ten minutes' *viva voce* examination on diseases of the eye, and was also given a subject (with an ophthalmoscopic lamp behind him) and an ophthalmoscope, and was asked to give my opinion as to the condition of the fundus.

I am, Sirs, obediently yours,

Nov. 28th, 1889. A. H. R.

"A HOUSEHOLD MAN-TRAP."

IN reference to our annotation last week with the above heading, Mr. G. Bird, of the Western Iron Works, Lancaster-road, Notting-hill, writes to say that his firm are manufacturing coal-plates to which a self-fastening arrangement is attached, which, unless loosened from beneath, prevents the removal or shifting of the plates.

BACTERIA IN MINERAL WATERS.

DR. G. MÜRGES of Dubuque, Iowa, following the example of Dr. Reinl of Franzensbad, has examined bacteriologically nineteen different varietics of American mineral waters (*Journ. Amer. Med. Assoc.*, Nov. 16th, 1889). He thus sums up the results of his inquiry:—

"1. The bacteria in bottled mineral waters are probably not derived from the spring in the majority of cases, but are due to contamination from the bottles and corks, the cleansing methods now in vogue being insufficient to destroy them.—2. Carbonic acid in a bottled mineral water has a powerful inhibitory influence on the development of germs, whether the gas is natural to the water or has been artificially generated and added to it. When the proportion of CO_2 is 350 cubic inches or more to the gallon, the retarding influence of the gas is very great. It is much less when the proportion is only 250 cubic inches to the gallon. But among every dozen bottles of even the most highly carbonated waters there is at least one which contains more than 250 micro-organisms to every cubic centimetre, and ten even out of twelve bottles may be thus contaminated. When the water is charged artificially, some time may be given for contamination before such charging is accomplished.—3. Sulphuretted hydrogen gas, in the proportion contained in mineral waters, probably has some inhibitory influences on the development of germs, but not to the extent which might be *a priori* expected.—4. As regards freedom from bacterial contamination, most of our native carbonated mineral waters are superior at least to several of the most popular European waters of the same kind.—5. The non-aerated, so-called, table waters are probably very inferior to ordinary hydrant water.—6. The strongly saline non-carbonated mineral waters are so badly contaminated as to be wholly unfit for internal administration in the form in which they are at present put up, unless the germs are previously destroyed by heating (for two hours at 70°C.—Reinl).—7. In order to bottle at least a non-carbonated mineral water in such a way that it will remain bacteriologically pure for an indefinite period, the bottles should first be boiled or steamed, kept in an inverted position in a place free from dust until cool, then immediately filled and closed with boiled corks."

Surgeon.—An F.R.C.S.Ed. is entitled to wear the gown which is the recognised collegiate robe of the Fellowship. When or where is a question which must be left to individual taste.

S.—We have no recollection of a statement of the kind having appeared in our columns.

Mr. J. R. Wallace.—The University of Cambridge, amongst others.

Dr. J. Wilson (Liverpool).—The book is a valuable one.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Bryant, London; Professor Marshall, London; Dr. Steavenson; Sir G. H. B. The Bradshaw Lecture

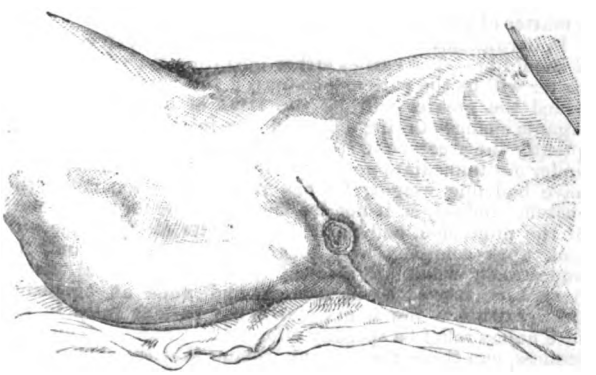
ON

COLOTOMY, LUMBAR AND ILIAC,

WITH SPECIAL REFERENCE TO

THE CHOICE OF OPERATION.



Delivered at the Royal College of Surgeons on December 5th, 1889,

BY THOMAS BRYANT, F.R.C.S., M.CH.,
VICE-PRESIDENT OF THE COLLEGE.

MR. PRESIDENT AND GENTLEMEN,—For the honour you have conferred upon me by nominating me your Bradshawe lecturer I offer you my best thanks; and I trust I shall be fulfilling the intentions of the founder of this lectureship by selecting a surgical question for consideration. The subject I have chosen may fairly be said to have come into notice during the lifetime of Dr. William Bradshaw of Reading (to whose memory this lecture was instituted in 1880), and to have grown rapidly into prominence since his death. The subject to which I wish to draw your attention is that of Colotomy, and I propose to consider it chiefly with reference to the form of operation which should be selected. It is not my intention to enter at any length into the history of the operation, for such would be wearisome; but I must remind you that while Littré in 1710 *suggested*, in the "Memoirs of the Academy of Sciences of Paris," the performance of the iliac (miscalled inguinal) or intra-peritoneal colotomy for the relief of infants born with imperforate bowel, the idea was not practically applied for eighty-seven years, when Pillore of Rouen in 1797 opened the cæcum in the right iliac fossa; and that while Callisen of Copenhagen *proposed* the extra-peritoneal operation of lumbar colotomy in 1798, it was not till 1839, when the operation was taken up and carried into effect by Amussat, that colotomy can in any sense be said to have found a place in the practice of surgery. The practical adoption of the operation was, however, very slow so far as London was concerned, for in October, 1859 (that is, twenty years after Amussat's success), or thirty years ago, when I undertook my first lumbar colotomy in a patient of the late Dr. Thomas Addison, the operation had been undertaken but once at Guy's Hospital, and that was by Mr. Hilton ten years previously;[1] and I am not aware that it had at that time been performed at any other hospital. Indeed, it may with all truth be said that the operation in both its varieties was then regarded with scant favour by the general body of the profession.

It may have been occasionally sanctioned as an operation for the relief of congenital rectal malformations when other measures had failed or were inapplicable; and to bring about this practice Mr. Curling's paper of 1860[2] had an undoubted influence; but as a means for giving relief to patients suffering from chronic intestinal organic ulceration or obstruction, from whatever cause, it was generally, and, indeed, I may say is still too much regarded, as a *dernier ressort*, and, as a consequence, it was as a rule only carried out when all other means had been tried and proved to be useless. This position of colotomy I, in common with some few other surgeons, have, however, never accepted. We have held a more favourable view of its capabilities both as a life-saving as well as a reliable palliative measure. We have regarded it as the best means the surgeon has at his disposal for the relief of rectal obstruction from cancerous and other disease which is not otherwise removable; and experience has proved that life may by it be saved when the disease is not cancerous, and prolonged even for years when it is so. Experience has likewise taught us that where these good results are not to be expected, what remains of life will be made more endurable; for the local disease which is the cause of the obstruction makes much slower progress and becomes a source of less distress as soon as the fæces are diverted from their normal course, and as a cause of irritation are removed. Within the last ten years there has consequently been a remarkable advance in the position of colotomy as an operation for the relief of rectal stricture, and at the present day the value of the operation is not only fully recognised by an increasing number of surgeons, but a warm discussion has arisen as to the operation which should be performed; indeed the casual reader of the journals and periodicals might be led to think that the lumbar or extra-peritoneal measure, which has hitherto found most favour, was becoming obsolete and doomed to give way to the iliac or intra-peritoneal method. For, at the present time—where in this branch of surgery, as in so many others, we see a measure of success follows modern practice, which by the old could never have been anticipated; when old landmarks are removed, and new ones are being laid down; it may appear to the skilful and ambitious as if "all things seem possible"—and under such circumstances it behoves us to take stock of facts and see whither we are tending, in order that the old paths be not blotted out by new without a good reason, and that change should not be mistaken for improvement; for caution must still be the surgeon's motto, and venturesomeness his rock of offence.

I propose in the present lecture, therefore, to compare the value of the lumbar or extra-peritoneal with the iliac or intra-peritoneal method of colotomy, and so utilise the experience I may have had of one or both operations, to help towards the solution of the important practical problem as it now presents itself. I would premise, however, in order to make clearer what I shall have to notice later on, that I have for many years always employed the oblique incision for lumbar colotomy (see engraving). For this line of incision not only follows the course of the nerves and vessels and allows room for all necessary manipulation, but falls

naturally into the fold of skin above the crest of the ilium, which is constant in all, and well marked in fat, people. This fold, I have reason to believe, acts beneficially in preventing the prolapse of the bowel which surgeons who employ other lines of incision are said to complain of, and at the same time tends to keep the artificial anus closed. When the bowel is exposed, I separate it carefully with the fingers from its upper and posterior attachments, and so allow it to bulge well out of the wound. When it is not over-distended, I, with a finger gently introduced at its posterior border, hook it well out of the wound, and rotate it inwards, in order to expose its posterior longitudinal band to view. I then and there fix it to the margins of the skin wound. Should the symptoms be urgent, I open the bowel at once, after having passed two sutures with a long straight needle through the integument and bowel, and given them into the hands of an assistant to hold and to keep tight. I open the bowel between these sutures, and as the contents of the bowel escape keep a stream of iodine water flowing over the part. With an aneurysm needle or finger inserted into the lumen of the opened bowel, I then draw the centre of one suture out, divide it, and with the divided suture fasten the opposite borders of the bowel to the skin wound, and deal with the second suture in a like way. A free opening is made into the bowel. The bowel is fixed subsequently with two or more sutures, and, as a rule, the inner border of the wound is left open for drainage purposes, particularly if the patient be very fat. When there is no need or urgency to open the bowel at the time of operation, I leave it *in situ* for three or more days. In some cases I stitch the projecting unopened bowel to the margin of the wound; in others I transfix it with long pins.

[1] Guy's Hospital Reports, 1849.
[2] Royal Medico-Chirurgical Transactions, vol. xliii

Digitized by Google

The former practice seems preferable in fat subjects, where the wound is deep; the latter in thin subjects where the bowel can be well drawn out. I never fix the bowel to the muscle. In two or three cases in which I have transfixed the bowel with pins I have had some slight local inflammation and suppuration from the escape of fæcal air at one or other of the points of puncture; but this complication has never been the source of any serious detriment. The practice, indeed, is so simple and satisfactory that I do not regard this objection as one of any importance.

I do not propose to make much use of or to rely upon statistics in the question before us—for the value of an operation like colotomy is no more to be estimated by statistical results than is that of herniotomy, and yet the value of herniotomy is never questioned. The immediate success or failure of both operations turns but little upon the operation itself if well performed, but upon two main points—the first being the local condition of the bowel above the seat of obstruction in colotomy, and at the seat of strangulation in herniotomy, and the second upon the general condition and age of the patient when submitted to either ordeal. In both cases, if from procrastination, serious intestinal changes have taken place before relief is given, recovery is hardly to be expected. In both cases, if these changes are but slight, recovery may be looked for; and yet again in both cases, if from old age or organic visceral disease feebleness be present, success will not be obtained; for where patients have, from whatever cause, no reserve of power at the Bank of Health upon which to draw in an emergency, the repair of parts injured by disease or operation becomes impossible. It is clearly evident, therefore, that in colotomy, as in herniotomy, the period at which either operation is undertaken, with respect to the changes in the bowel involved in either the obstruction or strangulation, is a matter of primary importance.

In herniotomy this truth is fully recognised, in colotomy it should be. The earlier either operation is performed the better will be the patient's chances; the longer it is postponed the greater will be the risks of serious incurable organic changes taking place in the intestine, and consequently the greater the risk to life. In the operation now under our immediate notice can it be said that these truths have had due weight, for has it not been too much the custom—indeed, is it not too much so now for a large part of the profession, and particularly of its medical side,—to look upon colotomy as a measure which should only be undertaken when all medical and other surgical means have been proved to be useless, and when an agonising death within a few hours stares the patient fully in the face unless relief be speedily afforded? Under such circumstances, can there then be any wonder that the statistics of both the extra- and intra-peritoneal forms of operation appear at first sight to be so bad, and that those of Erckelen, carefully compiled up to 1884, are made by Treves to show that thirty-eight in every hundred cases of lumbar, and forty-six in every hundred cases of iliac colotomy died within twenty-one days of the operation, though probably, I may add, not from it. To my mind it is, however, a matter of wonder that the mortality of the operation was not higher, for considering the circumstances under which most, if not all, of these operations were undertaken—that is, as a last resource,—the prognosis in all must have been most unfavourable. I believe, therefore, that the statistics I have quoted should be read in another way, and that it should be recognised that 62 per cent. of the cases of lumbar and 54 per cent. of the cases of the iliac operation were rescued from the grave, since it is more than probable that all the cases which were operated upon would have been undoubtedly lost if colotomy in one of its forms had not been performed. In fact, it may with truth be asserted that in spite of the adverse circumstances in which the operation was undertaken, the large majority of the patients gained by it a considerable addition to their lives, whilst those that sank within the month found relief, and were saved from the intense miseries of a death from obstruction, and died peacefully.

Author's cases.—I should here say that I have performed lumbar colotomy in 170 cases, and that all but ten were on the left side. One hundred of these were urgent cases, and the operation was undertaken to ward off impending death; of these fifty-five were successful, and forty-five sank within the month. These last are the cases I have described as "too late cases," since it is fairly certain that if the operation had been considered and undertaken at an earlier period of obstruction, and before death stared the patient in the face, many months of life would have been given to each sufferer, and much severe distress would have been saved.

LUMBAR COLOTOMY CASES FOR CANCER.

One hundred urgent cases, of which fifty-five were successful.

45 died within the month (too late cases).
18 died within twelve months.
19 lived between one and two years.
12 lived between two and three years.
6 are now alive—3 between two-and-a-half and five years after operation; 1, six years.

Seventy not urgent cases.

Not one died within the month.
18, or 15 per cent., died within twelve months.
24, or 34 per cent., lived between one and two years.
16, or 22 per cent., lived between two and three years.
12, or 17 per cent., are now alive, and 8 of these from two to six years after the operation.
38 per cent. of the whole number have survived the operation from two to six years.

Of the fifty-five successful urgent cases, eighteen, or about one-third, survived the operation a variable number of months, but died within the year; another third lived between one and two years; twelve lived from two to three years; six are now alive, three, two and a half, and three years respectively after operation, and one, a lady aged seventy-one, upon whom I was persuaded to operate nearly six years ago with the sole view of giving relief to the agonising pain she was enduring. She was so feeble that I never thought it possible she could live many hours; by good nursing and the careful guidance of her medical attendant she, however, made an uninterrupted recovery, and is now apparently well and suffering but little from her rectal disease.

Seventy cases were operated upon before obstruction threatened life and with the object of giving relief to the constant effort to pass stools and to the pain which was associated with it. Not one of these cases sank from the operation; all convalesced and expressed themselves as grateful for the relief which the operation had afforded. When death came it was painless and from exhaustion—euthanasia. Eighteen of these cases, or about a fourth of the whole number, died within twelve months. Twenty-four, or about one-third, lived between one and two years. Sixteen lived two and three years. Twelve are now alive, eight having survived the operation from two to six years. Another ten or more cases which have been operated upon during the last twelve or eighteen months are alive and going along comfortably. These are not included in the above list.

I should say that in at least three-fourths of the patients who convalesced from the operation and experienced its benefits the artificial anus was a success—that is, that the whole of the fæces were discharged through it, and the local disease was left unirritated by the passage of fæcal matter. In the remaining fourth this desirable result was not secured, and fæces at times—particularly when they were liquid—passed downwards, and added to the local irritation of the obstructing disease. Relief was, however, afforded to all these patients by the use of cleansing enemata, injected sometimes from the rectum below, and sometimes from the artificial anus above, and the subsequent introduction of a sedative suppository through either anus.

With these observations upon my own experience, which I thought well to place before you at this period of my lecture, I will now pass on to consider the relative advantages of the iliac or intra-peritoneal, and the lumbar or extra-peritoneal operation, for within the last few years it has become what I fear I must call the "fashion" to advocate the former as being in the words of one of its supporters "greatly superior to the lumbar method;" and the credit of forcing this question upon the attention of the profession must be mainly given to Messrs. Reeves, Herbert Allingham, Harrison Cripps, and Chavasse.

The chief grounds upon which these surgeons advocate the operation are as follows:—(1) That the iliac operation is in itself easier than the lumbar; (2) that by means of the abdominal incision the diagnosis in obscure cases may be verified before the bowel is opened; (3) that by it there can be no possibility of the surgeon mistaking the small intestines,

Digitized by Google

duodenum, or stomach for the large intestine, and that abnormalities of the colon do not mean failure of the operation, since the abdomen can by the inguinal wound be carefully searched; (4) that the bowel can readily be drawn out of the wound, and consequently firmly fixed to the skin without causing undue tension on the stitches; (5) that in lumbar colotomy there is frequently so much prolapse of the gut as to give rise to serious trouble; and (6) that the inguinal position of the wound is far more convenient to the patient for purposes of cleanliness as well as for the adjustment of pads, to guard against the escape of fæces and flatus.

I propose to examine these claims *seriatim*, and will do so in the light of clinical experience as supplied to us by the different classes of cases as they pass under our care, starting with the assumption that the diagnosis of rectal obstruction from cancer or other organic disease is clear. Now, cases of obstruction from rectal disease, cancerous or otherwise, as they come before the surgeon, may be divided into three great classes. The *first* includes cases which may be called *urgent*, since they are associated with acute general symptoms and severe abdominal distension. They are cases generally of annular stricture involving the upper part of the rectum. The *second* class includes cases of chronic obstruction, mostly of the lower half of the rectum without severe general symptoms, but with abdominal distension. The *third* class includes all cases of obstruction from stricture of the rectum, but not urgent, in which the symptoms are fairly well marked but without abdominal distension. To each of these three well-defined classes of cases the operation of colotomy has its own special relation.

Is, then, the iliac or inguinal operation easier than the lumbar? Let us inquire. When applied to the first two classes of cases in which great abdominal distension exists, whether with urgent symptoms or otherwise, the difficulties of an iliac operation cannot be trifling. The advocates of the operation may make light of them, but they exist, and the dangers associated with them cannot be ignored. The chances and risks of protrusion of the small intestine as soon as the peritoneum has been opened are real, and if the large intestine has to be searched for, or the abdomen explored for diagnostic purposes, these dangers must be much enhanced. Should the large bowel appear at once at the iliac wound, the operation, it is true, would be much simplified, but this, it is admitted by its advocates, does not always occur; and when it does, the free manipulation of the bowel which is recommended, and to which attention will be drawn later on, would be both difficult and dangerous. In the third class of cases in which the abdomen is undistended or flaccid, the difficulties of finding the bowel would be slight. On the other hand, a distended abdomen becomes in the operation of lumbar colotomy a condition of advantage, and the searching for the colon, under these conditions is, as a rule, by no means a serious matter. If the patient be fat, there is doubtless at times some trouble, but if the surgeon directs his search forwards towards the reflected peritoneum, and not backwards, into the lumbar fat, and at the same time rolls his patient over from the semi-prone position in which he may have been placed for operative purposes, into the semi-supine, so that the bowel may mechanically fall back towards the lumbar wound, this difficulty will be diminished or overcome. In cases in which the bowel is wholly or partially empty the same practice is also of use.

In the iliac operation, however, if the difficulties be really less than those that have to be encountered in the lumbar, the risks which necessarily appertain to the mere division of the parietal peritoneum must be taken into account, even by the surgeon who admits to the full the impunity with which the healthy peritoneum may be surgically treated. In lumbar colotomy it can only be in exceptional cases that the peritoneum is opened; and should it be so, there can be no more difficulty or danger in dealing with the wound in the lumbar operation than there is said to be in the iliac. In both the risks of peritonitis must, however, be run, whatever those risks may be.

I may say that in the 170 lumbar colotomies that I have performed, I have but twice, knowingly, opened the peritoneal cavity, and in those two cases no harm followed. I am compelled, therefore, to conclude that the iliac operation is not easier than the lumbar when abdominal distension is present, although when the abdomen is flaccid, such may possibly be the case. To open the abdominal cavity to search for and find the colon may be an easy measure; in the cadaver it certainly is so, and possibly it may be said to be more so than exposing the colon in the right or left loin. But from the patient's point of view—which is the only right one—can it be truly said that the division of the peritoneum and the searching with the finger in the peritoneal cavity for a bowel which is diseased or suffering from congestion, the secondary result of disease, involves no more risk to life than the simple exposure of the colon in the loin outside the peritoneal cavity in the lumbar operation? When the parietal incision has been made in the iliac operation, Mr. H. Allingham states that in about half of his cases, and Mr. Cripps writes that in about a third of his, the large intestine presented at once; hence the conclusion is evident that in the remaining half or two-thirds of the cases, the bowel had to be searched for by the finger in the peritoneal cavity. Mr. Allingham goes on to show us how this should be done. These are his words: "When the large intestine does not present itself, I pass my finger into the abdomen, sliding over the iliacus muscle until I arrive at the intestine, which I hook up to the opening with my finger and thumb. If this manœuvre fails to find the gut, I search towards the sacrum, feel for the rectum, and trace the gut up; should this not succeed, the finger must be passed upwards towards the kidney, and the descending colon felt and traced downwards." Mr. Cripps writes: "If any other viscera than the colon present, they must be pushed back and the colon sought for by the finger. Sometimes it can be detected by the hard scybalous masses within it, or it can be traced up after passing the finger into the pelvis and feeling for it as it crosses the brim. The colon being found, a loop of it is drawn into the wound." In the cadaver, and possibly in a patient with a flaccid abdomen and viscera undistended, uncongested, and uninflamed, the manipulations which I have just described may be simple to the surgeon, and they may possibly not prove dangerous to the patient; but with an abdomen distended, and viscera which are undergoing the secondary changes which so soon follow long-existing obstruction, this searching process, as quoted above, can neither be free from danger to the patient nor free from difficulty to the operator; whilst in lumbar colotomy this visceral searching process in the peritoneal cavity can never be required, except on very rare occasions; for on the completion of the parietal wound and the division of the deep fascia, in at least two-thirds of my own cases—and particularly when the bowel is distended, artificially or otherwise,—the colon presents at once, and under these circumstances, after the fat and connective tissue are gently separated from the bowel by means of the fingers, the bowel is readily made to protrude through the wound, to which it is secured. In fat subjects it is true that the exposure of the colon may not prove such a simple process as that described, and when the bowel is empty some difficulty may be experienced; but if the bowel be sought as already described forwards towards the lateral reflexion of the peritoneum from the bowel, and the empty bowel be inflated by Lund's inflator, this difficulty is lessened and overcome. But under no circumstances can the searching process in the lumbar operation be made to involve such important parts as are of necessity implicated in the iliac, although to the surgeon it may prove trying.

It is true, that if the iliac operations were always undertaken before obstruction had become a prominent symptom, and before abdominal distension had taken place, the searching process would doubtless be simplified and rendered less dangerous, although in lumbar colotomy the same conditions would be equally favourable. So far therefore as the searching for the bowel in the operation of colotomy is concerned, it must be concluded that the lumbar method in the majority, if not in every case, has the advantage.

The *second* argument which the advocates of iliac colotomy advance in its favour is that by the iliac incision the diagnosis in obscure cases may be verified before the bowel is opened. But may I ask, has this objection any real weight, and is there in the majority of cases much, nay, any, doubt as to the diagnosis of rectal or colic obstruction? In a large proportion of cases the disease is within finger-touch, and then where is the doubt? Where the hand fails to reach, have we not in the history of the case, in the general symptoms, and in the local symptoms, and particularly where ballooning of the rectum is present,[3] ample evidence to justify the formation of a working diagnosis upon which to base a definite line of treatment? and when the exact seat of the obstruction is not to be made out by the clinical phenomena, have we not

[3] THE LANCET, Jan. 5th, 1889.

Digitized by Google

abundant pathological knowledge which tells us, in no uncertain way, that in four-fifths of the cases of obstruction the disease is situated below the splenic flexure, and consequently below that part of the colon which would be opened by a left lumbar colotomy, and that in the remaining fifth of the cases a right lumbar operation would almost to a certainty suffice to give relief? May I ask, therefore—should a rule of practice which has hitherto answered for the relief of chronic rectal obstruction be altered to suit the exceptional and not the average case, and should the general practice of surgery be moulded by exceptional cases?

The *third* reason which has been adduced as an argument in favour of iliac colotomy is that by it there can be no possibility of the surgeon mistaking the small intestine, duodenum, or stomach for the large intestine; and that abnormalities of the colon do not mean failure of the operation, since the abdomen can by the inguinal wound be carefully searched. The first half of this argument may have weight with some minds, but it does not recommend itself to my own. I do not regard it as a fair one, for the mistakes to which attention has been drawn are clearly due to errors of judgment or carelessness which belong more to the operator than the operation; and in estimating the value of an operation we are bound to assume that the surgeon is reliable. Errors of all kind must creep into all work, and particularly into surgical work, but they cannot be legislated for. May I ask, are mistakes in iliac colotomy quite unknown? Has the small intestine never been opened in error? With respect to the abnormalities of the colon, about which so much has been written and said, and upon which the advocates of the iliac operation base an argument against lumbar colotomy, I hardly know what to say. That such may occur, I, as an anatomist, must admit; but if so, I presume to suggest that this same chance of abnormality may occasion trouble in the iliac as in the lumbar method, although such may possibly be of a different form. But in a surgical point of view is the chance of an abnormality of the colon being present an argument which should tell more against lumbar than iliac colotomy? My own experience says no, with no uncertain sound, since out of my 170 cases of lumbar colotomy I have not met with any instance which gave rise to a serious trouble, or that rendered the operation in any way a failure. On one occasion I had to increase my oblique incision forward and pick up the colon at the brim of the pelvis, thus opening the peritoneum; but I subsequently restitched the edges of the peritoneum to the bowel and completed the operation as usual, and with a good result. With this experience, therefore, whilst we may admit the possibility, we may, I think, fearlessly dismiss the probability of the presence of any abnormality of the bowel from our minds, and regard it with no more fear than we do the risk of meeting with an anatomical irregularity in any operation upon an artery for aneurysm or other purpose. In a surgical point of view the risk need not influence practice, and certainly should not tell against the lumbar operation.

The *fourth* argument adduced in favour of the iliac operation, "that the bowel can readily be drawn out of the wound and consequently firmly fixed to the skin without causing undue tension on the stitches," is in a measure true; but it applies more to the condition of the large bowel when empty than it does to that of a patient the subject of obstruction, since a loaded bowel could hardly be thus manipulated. An empty sigmoid flexure can, however, when seized be readily drawn through the iliac wound to the extent of many inches, whereas an empty colon can at the most be drawn out through the lumbar wound to the extent of three or four inches. But is this free extrusion of the bowel at either the iliac or lumbar opening a matter of primary importance? is it essential for the formation of a spur deep enough to prevent the passage of fæces past the artificial opening into the bowel below, and so down the gut to the seat of disease, where it may become a source of local irritation and pain? Mr. Herbert Allingham and Mr. Harrison Cripps, the two most prolific writers upon this subject, say it is; but of this I think evidence is wanting, since my own experience tells me that this result can usually be brought about by much milder measures than those suggested and carried into practice by the advocates of iliac colotomy.

In my own practice of lumbar colotomy, in which an oblique parietal incision is its leading feature, I have been able to secure this result not only in the majority of cases in which I have been called upon to operate at a stage of the disease in which the symptoms were not urgent and the colon was not overloaded, but in a large proportion of the urgent cases undertaken for obstruction. This result has been secured by separating the colon from its posterior lumbar attachments by means of the finger; drawing it well out of the wound; and so rotating it forwards as to bring the posterior wall of the bowel with its longitudinal band to the surface, and there fixing it. In some instances this desirable result was secured rapidly after convalescence, in others it was not obtained for several months, and in three or four cases I have had to enlarge the wound backwards towards the kidney to bring it about. The strongest evidence I can bring forward to support this practice is, however, found in the fact that in three examples of recto-vesical fistula upon which I have operated and in which the passage of fæces and flatus into the bladder caused intense distress, neither fæces nor flatus passed downwards into the bladder within a few weeks of the operation, although in two of the cases urine occasionally passed at night from the bladder upwards, and escaped out of the lumbar wound. One of these patients lived eighteen months after the operation, a second lived seven years, and the third was known to have been alive and well fifteen years later. I have likewise many patients now going about the world enjoying life in comparative comfort who are never troubled by the passage of fæces downwards to the seat of disease. It is true that this desirable condition is not always to be secured, and more particularly when the operation has been undertaken with a bowel over distended, under circumstances of urgency, and when the surgeon is unable to bring about the required extrusion of the colon through the wound. But even in these cases there is not always any very serious distress, particularly if the rectum and the lower part of the bowel be kept empty by the use of cleansing enemata followed by the introduction of a sedative suppository; for with the artificial anus established above the seat of obstruction, the straining and forcing of the bowel, which previously may have caused much distress, are done away with, and as a consequence there is comparatively little pelvic pain. Indeed, even a foreign body may rest for months at the seat of obstruction without giving rise to any serious symptoms; for I have here [showing the specimen] a rubber plug which was, from carelessness on the part of a medical patient, allowed to pass from the colotomy wound downwards into the rectum to the seat of disease, and which remained in that position for twenty months without giving rise to any trouble, and was then expelled upwards by the action of the intestine and out of the colotomy wound, when the history of the lost plug was obtained. It may, therefore, be said that in the majority of cases of lumbar colotomy a sufficient spur is commonly obtained by the simple measures I have been in the habit of employing and which I have just described.

Before leaving this question of spur, I must allow the advocates of the iliac operation to explain their practice; and I shall do so by using their own words. Mr. Herbert Allingham, in the last edition of his father's work on Diseases of the Rectum, as well as in papers of his own published in the *British Medical Journal* for Oct. 22nd, 1887, and April 27th, 1889, goes fully into the way he believes this spur is to be obtained, and at the same time points out by what means the serious prolapse of the bowel which he admits frequently follows the iliac operation, can be best guarded against. Mr. Cripps also describes his method in the same journal for April 27th, 1889. "When the gut is found," writes Mr. Allingham, "and brought to the surface, I look for a piece with a sufficient mesentery, by passing the gut through the fingers; of course this can only be done if the disease is in the rectum, or lower part of the sigmoid flexure. Generally the part of the sigmoid first pulled up has quite sufficient mesentery. If it is fixed to the back of the abdomen, there being a very short mesentery, I pull up as much of the gut as possible, and stitch it to the wound, so that the intestine when opened (some days later) looks like the orifice of a double-barrelled gun. This appearance is obtained by introducing the suture in the following way:—A needle threaded with carbolised silk is passed through the mesentery, close to the intestine, then through the abdominal wall on both sides at the middle of the wound, and the sutures are tied up tight. If there is little or no sigmoid mesocolon, I am obliged to pass the sutures through the muscular and serous coats of the gut at its posterior part. Leaving a fair-sized knuckle of loose gut outside the wound, I next sew the gut all round to the skin, passing the thread only through the muscular

Digitized by Google

and serous coats. This is done carefully, so as not to prick the mucous coat. Antiseptic dressings are then applied. The gut is not opened for two or three days, unless bad symptoms appear." Mr. Harrison Cripps writes: "The colon being found, a loop of it is drawn into the wound. In order to avoid *the prolapse which is likely to occur* if loose folds of the sigmoid flexure remain immediately above the opening, I gently draw out as much loose bowel as will readily come, passing it in again at the lower angle as it is drawn out from above. In this way, after passing through one's fingers an amount varying from one to several inches, no more will come. Two provisional ligatures of stout silk are passed through the longitudinal muscular band opposite the mesenteric attachment. These provisional ligatures help to steady the bowel during its subsequent stitching to the skin, and, moreover, are useful guides when the bowel is ultimately opened. They should be about two inches apart." I have quoted in full these two surgeons' remarks upon the methods they employ to bring about the required result, as my desire is to do them full justice; but I cannot fail to draw the conclusion that to carry out the practice as recommended, it is clearly intended, although it is not stated, that the operation of colotomy should be undertaken at an early period of disease, and before symptoms of obstruction have become marked, for the manipulations described could never be carried out with an inflated abdomen and distended and possibly injured colon, nor can they be said to be free from danger. The means these surgeons employ to obtain their object are far more serious, and in my view more dangerous, and, so far as evidence goes, not more successful than the simple measures I have already described as applicable to the lumbar operation.

The next or fifth objection that I have to consider which has been raised against lumbar colotomy has reference to the prolapse of the bowel, which is said by the advocates of the iliac method to occur after convalescence has taken place in the lumbar operation, and which is stated to give rise to serious trouble. I must assume that this objection is real and based upon facts, and is not theoretical; for my own experience does not allow me to support it in any way. Indeed, in only one out of my 170 cases has this complication arisen, and in it it was the distal end of the colon which was at fault. The prolapse was also readily controlled.

A certain amount of prolapse after lumbar colotomy must be looked upon as an advantage, and I never feel certain that my patients are safe from the occasional passage of fæces past the lumbar wound downwards into the rectum until it has formed. I like one equal in extent to that which normally takes place in the horse in the defecating act. Such a prolapse I have called the equine prolapse. To have the question of prolapse, therefore, raised as an objection to lumbar colotomy is somewhat comical, and more particularly when we read in the writings of the advocates of the iliac method of the very severe measures which are considered justifiable to guard against it. Upon this point Mr. Allingham writes: "Through the new opening in the groin the intestine protrudes, and is a source of constant trouble and discomfort. Some patients have told me that had they been aware of the possible sequela they would never have consented to undergo the operation. Their life is simply spoilt, and they are practically prevented from going about and mixing with the world at large in consequence of the constant protrusion of the mass." After this serious grievance has been noticed, he goes on to describe the measures he adopts to prevent this trouble from following the iliac operation, and these means are, first, the pulling out of the gut through the iliac wound by its lower end till no more can be made to protrude, and this is to be followed by the same treatment of the upper end. The mesentery is now quite taut, and a large bunch of intestine several inches in length has been drawn through the opening, and is allowed to rest upon the abdomen. This bunch is then at its neck carefully stitched through its mesentery and muscular and serous coats to the edges of the wound. Later on this mass is excised, and it is interesting to note that quantities ranging from three and a half to six ounces in weight of intestine can be removed, without, as Mr. Allingham adds, any apparent detriment to the patient." As a physiological experiment these facts are of interest, but surely from a purely surgical point of view these measures tend to magnify the dangers of the iliac operation. Mr. H. Allingham admits this to be the case, and "confesses that this supplementary procedure of cutting away so large a quantity of gut has materially increased the seriousness of the operation, although," he adds, "the exceeding discomfort occasioned by this possible procidentia necessitates a fair grappling with the circumstances."

Mr. Allingham fails, however, to point out what must be evident to his as to my mind, "that the pulling out of the gut through the iliac wound by its lower end till no more can be made to protrude, and this to be followed by the same treatment of the upper end," must, of necessity, bring the local disease for which the colotomy is made dangerously near the wound. For my own part, if the measures I have quoted be necessary to make iliac colotomy a success, I can hardly admit that the operation as a rule of practice should be chosen so long as we have at our disposal the old and approved lumbar method, the objections to which are very unreal, and which under no circumstances can be complicated with conditions which can require any such severe surgical measures as those I have described, and particularly if the case be treated early.

The last and sixth argument I have to notice which is raised against lumbar and in favour of iliac colotomy has reference to the position of the artificial anus; the advocates of the latter operation maintaining that the iliac anus is more convenient to the patient for purposes of cleanliness as well as for the adjustment of pads to guard against the escape of fæces and flatus. Now, is this wholly true? That it is so to a degree may be at once admitted, for with an anterior wound the necessary process of washing is more readily carried out than it can be with a lumbar opening, although with it the difficulties are not found to be serious. But can it be said that the escape of fæces and flatus from the iliac opening is more readily controlled by pads and instruments than it has been found to be from the lumbar? My own experience tells altogether the other way—for the loin is a fixed and firm position, and its condition is much the same so far as resistance is concerned at all times—a good pad and dressing can consequently be readily maintained *in situ* without trouble or inconvenience, and if the patient wear stays, this difficulty is lessened. With the iliac method these stable conditions of parts cannot be said to exist. A pad and bandage which is satisfactorily adjusted with the patient standing will require readjustment with the patient sitting; and the variable condition of the bowel itself must always keep up constant change. I have been consulted by several subjects of iliac colotomy upon this point, and found their grievance to be a real one, and more particularly since it is irremediable. In three cases of iliac artificial anus which I have had, the difficulty was insuperable. Upon this score therefore, as upon many others, I hold the lumbar operation to be the preferable.

There are also certain cases of rectal cancer in which iliac colotomy seems to be quite inapplicable—that is, when the disease is fairly high up and involves the bowel above the brim of the pelvis. In these cases iliac colotomy would be a failure, as the opening would be below the seat of the disease, or the colotomy wound would be too near the diseased structure to be a success, since the chances of the growth spreading to the wound would be great, and the complication most detrimental. In all cases of iliac colotomy for rectal cancer this fear is real; indeed, in the lumbar operation itself cases are not rare in which the lumbar wound has become involved from the extension of the rectal disease. On the other hand, there is a class of cases in which the iliac method may have the advantage, and that is when the diagnosis of the case is less clear than usual, and the position of the bowel uncertain. Of this I have had one example. The incision, as Mr. Cripps rightly states, acting at first as an exploratory procedure for diagnostic purposes, and later on as a remedial measure. But these cases are most exceptional, and, as I have already said, the practice of surgery must be based upon average cases and not upon rarities. By iliac colotomy also the surgeon may be more frequently able to turn the case into one of colectomy, or excision of the growth, than by the lumbar method. I have done this but once in all my lumbar operations, and that case is fully recorded in the Royal Medical and Chirurgical Transactions for 1882, vol. lxv. With these comments upon the objections which have been raised against lumbar colotomy, and the supposed advantages of the iliac method, I must now sum up my material; and to save time I have done so in the form of a series of propositions.

1. For the iliac operation to be a success, the large bowel should not be loaded with fæces, the abdomen be by no means

Digitized by Google

tense, and the symptoms of obstruction far from urgent; since under opposite conditions (such as those too commonly met with) its supposed advantages would hardly be demonstrated. The searching for the bowel would, moreover, be a serious difficulty; the free manipulation, extrusion, or excision of the bowel which is advised would be unsafe even if practicable, and the necessity of having to open the bowel upon its exposure would, when called for, add to the dangers of the measure. The iliac operation consequently would appear to be applicable to only a small class of cases. If, then, it can be said that iliac colotomy is an easier operation than the lumbar, when the large bowel is empty, the abdomen flaccid, and the symptoms of obstruction unpronounced, it can without hesitation be asserted that with a distended abdomen and colon and urgent symptoms the lumbar operation is the simpler of the two.

2. To search for the colon in iliac colotomy performed upon a patient with an undistended abdomen and free from all urgent symptoms may neither be difficult nor dangerous; but with the opposite condition, in which the bowel is damaged above the immediate seat of disease from prolonged obstruction, danger must exist, and such a danger must be added to that which appertains to the peritoneal wound. In lumbar colotomy neither of these dangers has to be met; such searching for, extrusion, and dragging outwards of the colon as is considered to be essential in the iliac operation is never requisite, since the spur which is considered to be so essential to guard against the passage of fæces past the artificial opening in the iliac method can in the lumbar be obtained by far simpler means.

3. The prolapse of the bowel at the artificial opening which has been adduced as an objection against lumbar colotomy does not rightly or of necessity belong to it. To judge by my own experience, it is imaginary. In the iliac operation the objection is admitted, and sought to be remedied by an operative measure which is in itself of far greater magnitude than any lumbar colotomy I have ever done or seen.

4. The fear of an abnormality of the colon rendering the operation of lumbar colotomy a failure is practically groundless. I have known it to occur but once in my own practice, and in that case the patient suffered no harm. Such a fear, therefore, need in no way tell against the lumbar measure.

5. The greater convenience of the iliac over the lumbar wound for toilet purposes may at first sight seem plausible, but this apparent advantage is more than counterbalanced by the greater difficulty that exists in keeping any dressing or compress in position over the anterior opening to prevent the escape of the intestinal contents than is ever experienced over the lumbar.

6. The final conclusion is, therefore, clear that iliac colotomy is not yet proved to be superior to the lumbar operation. In doubtful cases, in which an exploratory incision is required for diagnostic purposes, it may be useful, but such cases are very few; in all others, lumbar colotomy has advantages which stamp it as the better measure. The single advantage that I can see in the adoption of the iliac method is that the question of operative interference will have to be taken into account at a far earlier period of the patient's trouble than it has been hitherto the custom to consider the propriety of the lumbar operation; if so, we may soon see the valuable operation of lumbar colotomy take its right place in the practice of surgery, and good may come out of a fashion which has certainly not been a universal success.

I regret to say that the notes of my cases are not sufficiently full to allow me by statistics to support a valuable remark by Mr. Jessop, in his instructive paper on the Treatment of Cancer of the Rectum at the Leeds meeting of the British Medical Association in August last, although I am convinced that upon the whole he is right, and "that in cancer of the lower half of the rectum we have not much fear of the occurrence of complete stoppage, and that that which occurs may in the majority of cases be got over for a time by injections, the introduction of the finger, or of bougies, the use of laxatives, and the like; but that where the upper portions of the rectum are involved, complete blockage is almost certain sooner or later to appear." Mr. Jessop's explanation of this fact is also doubtless correct, and it is found in the anatomical relations of the upper and lower portions, for whereas the rectum as it approaches the outlet becomes more closely applied to the sacrum and pelvic wall, in its superior portion it is comparatively free, and thus the contractile action of the colon above is exerted with effect in forcing the contents through a contracted ring where that ring is fixed and immovable; whereas, when the narrowed portion is free, movable, and not attached, as it is when seated in the upper portions of the rectum, the efforts of the bowel above succeed only in invaginating or otherwise displacing the growth, often so as to enable us to make a complete diagnosis by bringing the disease within reach of the finger, and fail altogether in effecting any onward movements of the contents.

In cancerous disease of the lower part of the rectum colotomy is, therefore, called for more for the purposes of relief of local distress than for pressing obstruction; whilst in the cases of cancer of the upper part of the bowel, the same treatment is called for, again using Mr. Jessop's words, "as soon at least as the first symptoms of impending blockage appear, and in time to anticipate those further changes upon which the mortality of colotomy so much depends."

ON THE

OCCURRENCE OF ACUTE HÆMORRHAGIC NEPHRITIS IN SUPPURATIVE MENINGITIS.

BY GEORGE F. CROOKE, M.D. EDIN.,
PHYSICIAN FOR OUT-PATIENTS TO THE QUEEN'S, LATE PATHOLOGIST TO THE GENERAL HOSPITAL, BIRMINGHAM;
AND
EDWARD N. NASON, B.A., M.B. CANTAB.,
RESIDENT SURGICAL OFFICER TO THE GENERAL HOSPITAL, BIRMINGHAM; LATE HOUSE SURGEON TO THE LONDON HOSPITAL.

THREE cases of this nature have recently come under our notice, and being struck by the fact that the nephritis in all three seemed to be rather a direct consequence of the meningitis than a mere coincidence, we have been led to study them carefully as being of considerable pathological interest. The results of our investigations show that the nephritis possesses certain special characteristics which we think are worthy of record, since we are unable to find that attention has previously been called to any relationship existing between these two conditions. These three cases seem to represent three stages of one and the same pathological process—namely, an early, a more or less intermediate, and an advanced stage; and we propose to describe the cases in this order, submitting first of all the clinical and pathological facts of each case, and afterwards discussing the various points of interest bearing upon the pathological relationship of this complication.

CASE I.[1]—Harry C——, aged seventeen, a brassworker, was admitted to the General Hospital, Birmingham, under the care of Dr. Simon (acting for Dr. Wade) on July 17th of this year. He was in an unconscious condition, so that the following history of his illness had to be obtained from his mother. On the morning of July 15th, having been previously to all appearances quite well, he complained of headache and vomited once or twice. There was a vague history of his having had a slight blow upon the head some short time before, but it seems doubtful if this were of any importance. There was no history of any rigor. He was sent to bed and remained there until he was brought to the hospital. During the 16th he was delirious and refused his food. On admission his temperature was 104° F., respiration 28, and pulse 100. Skin dry and burning, tongue foul. He lay on his right side, taking no notice of his surroundings, but was very irritable when disturbed. There was no squint, paralysis, or muscular twitching. Pupils were equal and reacted to light. Bowels had not been open for three days. Urine was passed involuntarily, so none could be collected for examination.—18th: Vomiting continued. Urine saved this morning and found to contain blood and albumen. One-twelfth of a grain of pilocarpine was given at 12 noon and 7 P.M., after which he sweated freely, and his general condition seemed a little better. Bowels open after castor-oil enema.—19th: Still very restless and wandering. Urine report was as follows: Twenty-eight ounces; specific gravity 1025; deep amber, smoky, acid; urea 3 per cent.; cloud of albumen, blood, granular and hyaline casts.

[1] For the notes from which this case was abstracted we are indebted to Dr. Short, resident medical officer of the hospital.

Digitized by Google

One-twelfth of a grain of pilocarpine was repeated, and fifteen grains of bromide of potassium ordered.—20th: Boy extremely restless, necessitating special attendant.—21st: Tongue and teeth foul, dry, and covered with sordes. He is incessantly moving about in bed in an aimless way, groaning all the time. He passes his urine involuntarily; but all attempts to get the bowels (which had been confined since the 19th) open failed, though on one occasion two minims of croton oil were given. He did not sleep more than an hour last night. Pilocarpine repeated. Later on in the day the temperature began steadily to rise, reaching 105·8° at 10.30 P.M., and subsequently 107°. Muscular twitchings of both arms and legs, more marked on the right side, began with the rise in temperature. Temperature reduced to 104° by sponging.—22nd: Temperature still very high. Muscular twitchings continue. Death occurred at 6 P.M. At the post-mortem examination the meningeal vessels over the vertex were found engorged, but the dura mater was neither tense nor adherent to the calvaria. Lines of greenish-yellow lymph extended along the course of the vessels over the cerebral convolutions of both hemispheres, and the pia mater was adherent at places to the cortex. Diffuse patches of lymph were found on the dural arachnoid at the base of the skull in the middle and posterior fossæ, and extended some way down the spinal canal. These patches were not found over the base of the brain itself except in the two Sylvian fissures. The basal ganglia looked cloudy and hyperæmic, but the brain substance was fairly firm. Ventricles were dilated and contained an excess of clear serum. Microscopical examination of the meninges showed no evidence of tubercle. On the heart a few subendocardial ecchymoses were found, and there was slight hypertrophy of the left ventricle. The lower lobes of the lungs were congested; bronchial tubes full of muco-pus. The kidneys weighed 8¼ oz. Capsules a little sticky in places, but surface smooth. Venæ stellatæ engorged. On section, the organs looked hyperæmic, but cortex here and there a little more pallid than normal, with tendency to opacity. Punctiform and streaky hyperæmia, with some punctiform extravasations here and there on careful inspection. Otherwise no gross changes of extent or importance could be made out with the naked eye. The remaining organs presented nothing worthy of note. Histological examination of the kidney showed the following condition: General hyperæmia. The presence in the tubules, both of cortical and medullary portions of red blood-cells and occasionally hyaline and granular casts. Early cloudy swelling of the renal epithelium, more obvious in some than in other convoluted tubules; slight hyaline swelling of the walls of the glomerular capillaries, and the occasional presence of a granular and reticulated exudation within Bowman's capsule. In some glomeruli the capillaries looked abnormally dilated and were distended with red blood-cells, but no proliferative changes were noticeable in either the capsular or glomerular epithelium, at the most only slight swelling of it. The stroma appeared absolutely normal.

CASE 2.—George K——, aged twenty-four, was admitted into the London Hospital under the care of Dr. Sutton on Oct. 7th, 1886. He was then suffering from headache, pain in the abdomen, and general malaise. His temperature was 104°, face flushed, skin hot and dry, and he was delirious. For several days previously he had suffered from severe headache, and had vomited. There was no history of his having had any discharge from the ears, and his aunt, with whom he was living, stated that she had noticed that the urine was very dark on the day before admission, but not previously. The morning after admission he passed urine charged with blood, of which the following was the report. Specific gravity 1010, porter-coloured, acid, one-fifth albumen; blood casts, blood, and epithelial débris in large quantity. The following night, Oct. 9th, delirium was so excessive as to necessitate his being conveyed to a padded room. He had a distinct rigor that afternoon, his temperature rising to 105°. This was followed eight hours later by a second. These were repeated at intervals for the next two days, during which time the urine passed was similar in character to that voided the first day. There was no paralysis or muscular twitching, but restlessness and delirium were most marked, and produced a condition of extreme exhaustion, from which he sank on Oct. 13th. Post-mortem examination revealed a diffuse suppurative meningitis, involving the surface of the whole of the right hemisphere, and extending slightly on to the left. There was extensive disease of the middle ear on the right side, from which the suppuration had started. The right lateral sinus was thrombosed, and the thrombus breaking down. The kidneys were very large, dark, and intensely engorged, weighing eleven and ten ounces respectively. There were no pyæmic abscesses to be found in the kidneys or in any of the other organs, which, except that they were all more or less hyperæmic, presented no morbid appearances. On histological examination the most striking feature was the extensive hæmorrhage into the tubules, which in some instances seemed to have taken place directly through the basement membrane, from the engorged and probably ruptured intertubular capillary vessel; the epithelium was pushed away from the basement membrane by the interposition of red blood-cells. The glomeruli were uniformly swollen and mostly filled out their capsule; they showed nuclear proliferation and occasionally hyaline degeneration of the capillary tufts, but no exudation within the capsule. Parenchymatous changes were quite obvious, and consisted in proliferation and disintegration of the epithelium of the convoluted tubules as well as the presence within some of a granular or colloid exudation. The stroma was the seat here and there of small-celled infiltration.

CASE 3.—George M——, aged forty-one, was admitted into the General Hospital, Birmingham, under the care of Mr. Bartleet, on Nov. 24th, 1888, suffering from a small subdural abscess, the result of a punctured fracture of the skull, which he had sustained some months previously. The symptoms were purely local on admission. On Nov. 30th he was trephined, and a drainage-tube inserted.—Dec. 1st: Free purulent discharge from wound, slight twitchings in left arm and left side of face, accompanied by a sensation of numbness in these regions. Temperature 101°.—2nd: Temperature rose to 102°, but twitchings ceased. Patient complains of headache.—7th: Temperature has gradually fallen to normal, but there is great restlessness. A hernia cerebri has begun to appear.—10th: The urine, which had been carefully watched up till the day before and found natural, is this morning charged with blood. The following is the report: Specific gravity 1018, porter-coloured, dense cloud of albumen, chocolate-red deposit composed of large, coarse colloid and granular casts, small granular casts, epithelial casts, numerous red and white blood-cells, numerous hæmatocytes, and much yellowish-brown granular débris. Temperature has risen again to 101·4°.—12th: Cerebral symptoms, including muscular twitchings, headache, slow pulse (60), drowsiness, and marked wasting are steadily increasing. Urine voided only in small quantities; is similar in character to that passed on Dec. 10th.—14th: Headache very severe, and accompanied by pain in the back of the neck.—16th: Patient became quite unconscious yesterday, and died this morning. The urine up to the time of death still contained blood. The post-mortem examination showed that a hernia cerebri had protruded through an opening in the right parietal bone, a little in front of the lambdoidal suture, and around it an extensive purulent meningitis had developed, affecting both hemispheres, but especially the right, where the purulent exudation in the subdural space was fully $\frac{3}{16}$ in. thick. The pia mater was diffusely hyperæmic, and contained in its substance patches of lymph along the course of the cerebral vessels. There was only a very slight effusion of lymph found at the base of the brain. Except around the hernia cerebri, the brain substance on section appeared fairly normal, and contained no abscess cavity. Beads of pus were found in the choroid plexuses, and the ependyma was soft and infiltrated. The kidneys weighed 16 oz., and were typical examples of the large red-mottled kidney. The capsules separated easily. On section the glomeruli were more distinct than usual, appearing as minute glistening bodies. The heart weighed 10 oz. The lungs weighed 2 lb. 6 oz. The bases were œdematous and congested. The spleen weighed 4 oz.; it was soft and pulpy. The liver weighed 54 oz.; it revealed cloudy swelling, with slight fatty changes. Histological examination of the kidneys showed the nephritis to be an acute diffuse one of considerable intensity, in which the changes affected the glomeruli, parenchyma, and stroma almost equally. The glomerular changes consisted in general swelling and cellular infiltration of the capillary tufts, and in the formation within the capsule of a hyaline reticulum, enclosing in its meshes desquamated capsular epithelium, lymphoid, and a few red blood-cells. The exudation then appeared to undergo a rapid coagulative necrosis, and insinuated itself between the lobules of the tufts; it is not

Digitized by Google

infrequently accompanied by hyaline degeneration of the capillaries themselves. The afferent arterioles were swollen and compressed, both without and within, by cell proliferation; hyaline swelling of the intima was sometimes met with. The efferent venules were dilated and lined by swollen endothelium. Parenchymatous changes were equally prominent, and the intratubular exudation was of a varied character. The epithelium of the convoluted tubules was uniformly swollen and proliferating, it was coarsely granular, and often undergoing colloid degeneration. A most conspicuous change was the presence within many of the convoluted tubules of true fibrinous casts—that is, casts composed of either fibrin alone or containing in its meshes leucocytes and red blood-corpuscles. In this respect it much resembled the intra-alveolar exudation in croupous pneumonia. These casts appeared to undergo coagulative necrosis, and to melt down into homogeneous and highly refractive colloid material. Other tubules, notably Henle's loops, contained blood, cellular (lymphoid) and delicate hyaline casts. The intertubular stroma was infiltrated with œdema, and with leucocytes which were sometimes found disposed around Bowman's capsules.

Remarks.—It is now an accepted fact in renal pathology that the acute specific febrile diseases are answerable for a great number of the examples of acute nephritis that come under observation; and pathologists have classed them in a group which they have designated "febrile" or "infective" nephritis. The nephritis develops in the course of the disease, and in some instances, notably in scarlatina and diphtheria, constitutes an important clinical feature in the case. It is attributable in most instances to the operation of the same specific virus supposed to be responsible for the disease itself. Among the list of acute febrile diseases in the course of which a nephritis may develop suppurative meningitis has not hitherto been included, for the reason that, if it were noticed to occur at all, it was probably regarded as but another manifestation of general septic mischief. The points of interest in the nephritis presented by these three cases are twofold. First, certain peculiarities observed in its anatomical characters; second, its nature and pathological relationship to the meningitis.

I. Certain peculiarities in its anatomical features. 1. The feature common to, and most conspicuous in, all three cases is its strikingly hæmorrhagic type, shown by hæmorrhage of varying extent into the tubules, an extreme degree of which was found in Case 2. 2. The diffuse character of the inflammatory changes, of varying intensity in the three cases, but present in all. 3. Its resemblance to croupous pneumonia in the following particulars: in the engorgement with swelling of the epithelium, then in the fibrinous exudation,[2] with proliferation of the epithelium, and lastly, in the commencement of degenerative changes in the inflammatory products. 4. The absence of necrotic foci as indicative of capillary embolism (pyæmia). 5. The absence of micro-organisms (septicæmia). 6. The absence of any evidence of previous renal disease.

II. In attempting to discuss the nature and pathological relationship of the nephritis to meningitis, we must first draw attention to the origin of the primary disease itself. In Cases 2 and 3 the meningitis was manifestly septic, being secondary to ear disease in the one and to traumatism in the other, while Case 1 appears to have been, as far as we can determine, idiopathic and of a simple purulent character. In view of exception being taken to our idea that the nephritis was consequent upon the meningitis, we think that a few observations on the clinical aspect of the cases bearing upon this point might be made. In Case 1 we have no proof as to the priority of the meningitis. The knowledge of the condition of the urine collected on the second day altered the clinical aspect of the case, and made the diagnosis between some anomalous form of uræmia and meningeal irritation more difficult; but, in the absence of urinary suppression, and with the presence of marked delirium, the balance remained in favour of the latter. In Case 2 the evidence with regard to the priority of the meningitis is much stronger, while in Case 3 it is conclusive, so that it seems highly probable that this relationship also obtained in the first case. It is to be regretted that the previous history in Cases 1 and 2 could only be obtained indirectly, as in neither was the patient able to give any information concerning his previous condition or subjective symptoms. With regard to the nephritis, we are inclined to attribute it to the combined effect of two independent causes—namely, septic absorption and vaso-motor disturbance common to the various forms of meningitis. Much importance has of late years been attached to the demonstration of micro-organisms in the kidney as evidence of the infective character of the nephritis; and in certain forms of embolic origin, such as occur in pyæmia, ulcerative endocarditis, &c., they have been found by various investigators to be pretty constant, and not difficult of detection. This, however, is not the case in some of the other acute febrile diseases, such as scarlatina, diphtheria, enteric fever, &c., where the evidence on this point is conflicting.[3] We might here quote a remarkable example of acute nephritis occurring in a case of cancrum oris which one of us had the opportunity of examining some time ago. In this the inflammation was exquisitely catarrhal in type, and consisted mainly in proliferative and degenerative changes in the renal epithelium, and in the exudation into the tubules of a number of colloid globules of all sizes. A few slight patches of blood extravasation were found in the stroma, but were quite insignificant compared with the nature and extent of the parenchymatous changes. Now in this case micro-organisms of different species were found in profusion at the local seat of the disease, and some few in the heart, while, after the most patient search according to modern technical methods, we failed to discover any in the kidneys, liver, or spleen. But the absence in such cases of micro-organisms by no means excludes the influence of some toxic agent circulating in the blood, upon the presence of which we are obliged to fall back for a possible causal explanation, not only of the nephritis, but also of the morbid changes found in the liver and spleen. We have introduced this last case for two reasons. First, because it represents an example of acute nephritis in a disease pre-eminently mycotic in character, and distinctly localised at its commencement, in which the subsequent changes become generalised by the diffusion into the circulation of some toxic agent, not particulate, but probably chemical in its form. Secondly, because certain differences in the finer changes are expressed in the exquisitely catarrhal type of the epithelial changes and in the absence of hæmorrhage into the tubules. Although, therefore, we have not been able to satisfy ourselves as to the presence of micro-organisms in the kidneys of our cases of nephritis, still we are inclined to support its septic character on similar grounds, even if we omitted to search for micro-organisms in the meninges. It seems highly probable that the presence within the kidneys during the process of excretion of certain subtle chemical poisons of the nature of ptomaines or leucomaines, manufactured at the local seat of the disease and absorbed from the meninges, constituted the exciting cause of the tissue change, while the vascular change not improbably owed its origin to some obscure nervous influence directly connected with the meningeal irritation. That disturbances of the vaso-motor system are more or less constant features of meningitis is a recognised clinical fact, and is expressed by the peculiar flushes of the face, and by the "tache cérébrale" so graphically described by Trousseau. The balance of power and reaction between the vaso-dilators and the vaso-constrictors is disturbed, and this may affect the renal blood-vessels equally with those in other parts. When to that influence are added the effects of some poisonous ferment circulating in the blood, and acting directly on the walls of the blood-vessels of organs so essentially eliminative and excretory as the kidneys, it is easy to conceive that the balance of power might be still further disturbed by the changes produced. What the intimate nature of these changes may be is beyond the power of the microscope alone to reveal; the problem is a physico-chemical one, involving grave alterations in nutrition; but certain effects of them we know from Cohnheim's researches—viz., dilatation of the blood-vessels from loss of contractile power in their walls (paresis), their increased permeability, and the ease with which under conditions of increased blood pressure they allow red blood-cells to escape. We think that in this way may be explained the peculiarly hæmorrhagic character of our cases. We have examined the hos-

[2] We may here remark that although one of us has examined now a very large number of examples of acute nephritis, we have never before seen so many fibrinous casts as presented by Case 3. In Case 1 the nephritis is almost in its earliest stage.

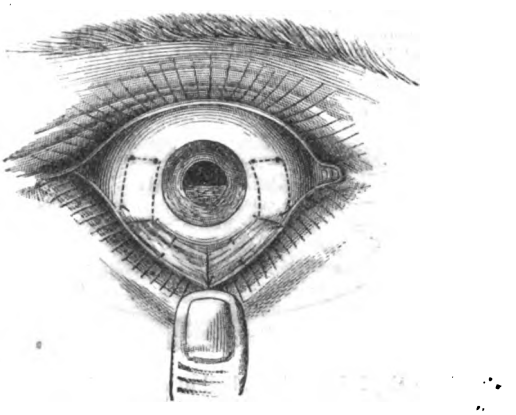
pital post-mortem registers for the last five years, and have perused the reports of twenty other cases of meningitis. Fifteen of these were tubercular and the remaining five purulent, but non-tubercular and consequent upon either ear disease or traumatism. In none did we find noted any gross changes of importance in the kidneys; in several instances they were described as somewhat hyperæmic and presenting evidence of cloudy swelling; these were chiefly the non-tubercular cases, in two of which the appearances were confirmed by the microscope, but no intra-tubular hæmorrhage was noticed. In the tubercular cases the kidneys were found of normal size, sometimes pallid and sometimes more or less congested, and in those cases where the tuberculosis was generalised the kidneys were preserved for histological purposes. On looking over some of the sections tubercles were seen, but no such changes approaching those we have just described. Accordingly, it would appear that our three cases are, to say the least, exceptional, and we could not pretend to formulate conclusions based on so limited a number. In our paper we have confined ourselves principally to the statement of facts, and in our attempt to discuss their significance have merely indicated our lines of thought; and should these be deemed worthy of such consideration as to arouse the attention of other observers in the same direction, we shall feel amply justified in their publication. In conclusion, we wish to express our obligations to Dr. Sutton of the London Hospital, and Drs. Wade and Simon and Mr. Bartleet of the General Hospital, Birmingham, for kind permission to use their cases.

Postscript.—Since sending our communication to the press we have met with the record of a case, similar in many particulars to our second, in the *Monatsschrift für Ohrenheilkunde*, 1888, No. 8, by A. Weichselbaum.[4] It is that of a woman aged fifty-two years, who was admitted into the hospital in Vienna in a comatose condition, and died two hours afterwards. The following conditions were found at the necropsy:—Acute rhinitis; purulent otitis media with perforation of the tympanum; ostitis and periostitis of the mastoid process, phlegmonous cellulitis and myositis of the sterno-mastoid on the same (left) side; myocarditis; acute swelling of the spleen; cloudy swelling of the liver; *acute parenchymatous nephritis*, and commencing pneumonia in the lower lobes of the lungs. Bacteriological investigations undertaken immediately after the necropsy showed Friedländer's bacillus pneumoniæ to be the only organism discoverable. It was pretty widely diffused, at least in the local lesions, to which there succeeded, in Weichselbaum's opinion, a general infection of the system, producing the changes noted in the viscera. Thus he believes the origin of the nephritis to be connected either directly or indirectly with the presence of the bacillus in the blood. It will be noticed that no meningitis developed in this case, neither is it mentioned that the nephritis bore a specially hæmorrhagic character.



Birmingham.

ON TRANSPLANTATION OF RABBIT'S CONJUNCTIVA TO THE HUMAN EYE.

BY J. R. WOLFE, M.D., F.R.C.S.E.,
PROFESSOR OF OPHTHALMOLOGY IN ST. MUNGO'S COLLEGE; SENIOR SURGEON TO THE GLASGOW OPHTHALMIC INSTITUTION.

WHEN the conjunctiva of the eyeball and the corresponding palpebral conjunctiva are destroyed by gunpowder explosion, by a burn with hot metal, quicklime, or other chemical substance, adhesion or symblepharon is the result. Iron moulders, puddlers, and labourers in chemical works being most exposed to such accidents, cases of symblepharon are frequently met with in towns like Glasgow. Numerous expedients used to be resorted to for the cure of this affection. They all had for their object the mechanical separation of the lid and eyeball, until the raw surfaces cicatrised. This surgeons tried to effect by repeated dissection and by keeping the surfaces apart by the interposition of foreign bodies, such as sealing-wax, leather, or glass shields. After repeated trials such measures were found useless. They are based on the supposition that a delicate physiological action can be replaced by a coarse mechanical contrivance. Abhorring friction of surfaces, nature frustrates such expedients, for, whenever the surfaces rub upon each other, they adhere and the foreign body is squeezed out by gradual constriction. I first used to try the radical cure of symblepharon by plastic operation of the conjunctiva. The operation consisted in taking a portion of the neighbouring healthy conjunctiva of the eyeball, and with it replacing the palpebral conjunctiva which had been destroyed. For experience has taught me that loss of the ocular conjunctiva, even to a very large extent, is generally regenerated without prejudice to the neighbouring tissues, whilst loss of the conjunctiva of the eyelid is followed by pannus, ulcerated cornea, and other lesions. (Fig. 1.) Fig. 1 represents the case of Simon M'K——, aged twenty, moulder, who, three years before he came under treatment, had his eye burnt with molten lead, resulting in adhesion of the lower eyelid, which covered the lower half of the pupil. I dissected the eyelid from the eyeball, separating it as far as the cul-de-sac, liberating the eyeball completely. I then passed two fine silk threads through each side of the conjunctiva at the outer aspect, which ligatures marked the breadth of the conjunctival flap to be removed. These two I put on the stretch, and with a pair of scissors I first cut horizontally, and then on each side of the ligatures; then putting the scissors behind, I cut it from the eyeball. The same process was followed on the inner side, and these two flaps were brought together in the middle line and secured with stitches, as marked in the diagram. The operation

FIG. 1.

was performed in September, 1869, and the case was shown some months later as a successful one in every respect.

Mr. Teale of Leeds introduced an operation similar to my own, and yet different from it in this respect: from each side of the ocular conjunctiva he takes a flap; "the one is stitched across the raw surface of the eyelid, and the other is fixed across the raw surface of the eyeball, and the two flaps are thus dovetailed into the wound." It is evident that in this operation a large supply of conjunctiva is requisite to repair a comparatively slight injury, while in my operation the conjunctiva of the eyeball is entirely disregarded, and the palpebral conjunctiva alone repaired. The result is that while Mr. Teale interferes only with a case of symblepharon, "provided it be of moderate extent,"[1] my operation is applicable to extensive adhesions, provided only that there be sufficient transparent cornea to make an artificial pupil, as shown in Fig. 2, which represents the case of John M——, aged fifteen, tinsmith, who had burnt his right eye with strong hydrochloric acid two years before, with the result of extensive symblepharon. The lower eyelid was covering the upper margin of the pupil; vision was therefore impossible. The first step accordingly was to make an iridectomy upwards and inwards, and two months later we proceeded to the plastic operation of the conjunctiva. But it will be seen that the lateral flaps were in this case impossible, because the lower extended above the meridian. I therefore took a large flap from the upper hemisphere of the eyeball, and secured it upon the eyelid, as above described.

There is a limit, however, to the extent to which we can go in borrowing conjunctival substance from an eye which has been previously injured. If we surpass that limit the

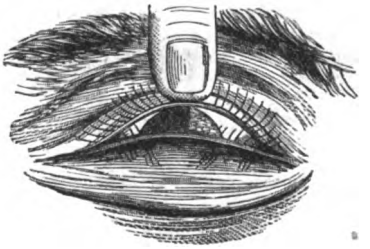
[1] Ophthalmic Hospital Reports.

Digitized by Google



corneal opacity may extend still further and our last chance of saving vision is lost. Indeed, we sometimes meet with cases in which the infliction of a new wound amounts to further disorganisation of the eye. As the operation already described is inapplicable in such cases, I was at one time

FIG. 2.

about to give up all idea of surgical interference, when i occurred to me that I might give the patient some chance by supplying him with conjunctival substance from the rabbit. One such case is represented in Fig. 3. Edward M'K——, aged thirty-one, iron-smelter's labourer, was, on Sept. 17th, 1872,

FIG. 3.

struck on the left eye by a ball of red-hot iron which caused disorganisation of the lower conjunctiva over the greater part of the cornea. On lifting the upper eyelid with the finger the sclerotic was seen, as it were, receding, and no dragging upon the eyeball could turn the upper border of the cornea sufficiently forwards and downwards even for making an iridectomy. The attempt to take a conjunctival flap from the upper hemisphere of the eye, as done in the previous case, was altogether out of the question, for there was no room to manipulate either with scissors or bistoury. In the same year I showed to the Glasgow Medico-Chirurgical Society this case, as my first successful case of transplantation. In August, 1875, I exhibited the same case along with another at a demonstration which I gave to a large audience at the annual meeting of the British Medical Association in Edinburgh. The second case was that of Peter Campbell, which shall be described presently. This operation has been generally adopted by surgeons of various countries. It is, in fact, due to the favourable results of transferring conjunctiva from the rabbit to the human eye that surgeons have become familiarised with the idea of borrowing tissues from the lower animals, and the principle has been further developed by the transplantation of nerve tissue from the rabbit to the human subject.[2] I deem it therefore necessary that the details of conjunctival transplantation should be well understood, for upon attention to these details the success of the operation depends.

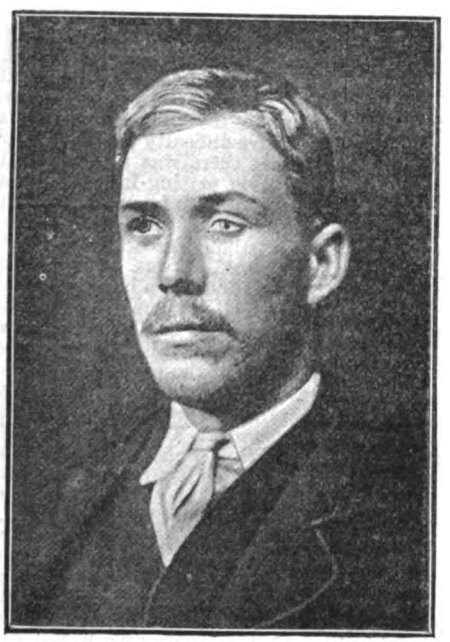
At the meeting of the British Medical Association in Glasgow in 1888, I had another opportunity of performing an operation in one case, and of showing another operated on five days previously, to enable those who were present to judge of the hopeless condition of an extensive symblepharon before and the results obtained after transplantation from the rabbit. This was the more necessary as, since first recommending it to the profession, I have considerably modified the procedure and rendered it more simple. From the account given in the journals of that date I extract the following:[3] "At the close of the meeting of the Ophthalmological Section on Aug. 10th, Dr. Wolfe gave a second demonstration at the Ophthalmic Institution, which was attended by London and foreign oculists. The subject was symblepharon; one operation was performed, and a patient operated on five days previously shown. In the case operated on, the lower lid was adherent to the eyeball, for the greater part of its extent the angle only being free. . . . The operation being successfully completed, the patient previously operated on by the same method was shown. One accident had completely destroyed the right eye, the left was also extensively damaged, only a small part of the cornea towards the lower and inner angle being transparent. An iridectomy had been performed there, and the extensive adhesions of both upper and lower eyelids rendered it nearly valueless. When the adhesions had been cut through, very extensive raw surfaces were found on both lids, on both of which the rabbit's conjunctiva had been implanted; and when the patient was shown, no doubt remained of the success of the operation. The eyeball was comparatively free and sight was good. In showing the patient, Dr. Wolfe commented on the fact that it was fifteen years since he introduced this operation, and in spite of the fact that the rabbit's conjunctiva gave perfect results, efforts to transplant mucous membrane from the human subject, from the mouth and even vagina, were being made."[4]

The operation is performed in the following manner:— 1. I first separate the adhesions by means of blunt-pointed scissors, so that the eyeball can move in every direction. The conjunctival sac and cornea are cleared of nodules, so as to obtain an even surface. 2. Two rabbits are then put under chloroform, one being kept in reserve in case of accident. 3. I take from the rabbit that portion of the conjunctiva, which lines the inner angle covering the "membrana nictitans," and extending as far as the cornea, on account of its vascularity and looseness. If the palpebral opening is too narrow, I enlarge it at the external angle, and introduce a ligature through the whole thickness of the free border of the lower lid, and by means of this ligature the lid is drawn open and kept steady, and the conjunctival cul-de-sac exposed. 4. Into the middle of the flap to be removed a black silk ligature is introduced, a knot is tied, and the ligature cut short. This knot is intended to mark the epithelial surface of the membrane, for without it the flap is apt to curl up, and leave us at a loss how to adjust it. 5. Next, I mark the boundary of the conjunctiva of the rabbit which I wish to transplant by inserting four black silk sutures, which I secure with a knot. The ligatures having been put on the stretch, I separate the conjunctiva to be removed with scissors, and, by means of a fine spatula, I spread it upon the back of my left hand. The four ligatures are then cut off, and the conjunctiva trimmed to the requisite size. It should be larger than the lost substance. 6. I now return to the patient, and see that the bleeding has subsided, and that the parts are in a fit condition to receive the transplanted flap, which has in the meantime become dry like a piece of parchment, and adherent to the dorsum of the hand. 7. It is then lifted by means of a spatula, and transferred to replace the lost conjunctiva of the patient. It is secured in its place by six or eight ligatures, or even more if necessary. This is a very difficult process, requiring delicate manipulation, and the assistant must keep the flap in its place by a spatula while it is being

[2] Nerve transplantation from animal to man. A novel operation is reported from Vienna as having been performed by Dr. Gersung on the person of Professor von Fleischel, who accidentally wounded himself sixteen years ago while performing a post-mortem examination. The result was severe inflammation of the right upper limb, which was followed by the formation of neuromata on various branches of the median nerve, to relieve the pain of which resection of the nerve at various sites was resorted to, causing anæsthesia of the parts supplied by it. Fresh neuromata, however, occurred, and finally the pain became so severe that a further operation became necessary. On March 4th the patient was anæsthetised, and the neuroma, which was situated behind the volar-carpal ligament, was excised. A piece of the sciatic nerve of a freshly killed rabbit was then obtained and sutured to the end of the cut nerve and to the connective tissue between. Healing took place by first intention; and as two months have now elapsed since the date of the operation and the pain has not returned, it is hoped that the so far favourable result will prove to be permanent. Sensation is gradually returning in the anæsthetic areas. [3] Medical Press, 1888.

[4] Prof. Snellen (Utrecht) has lately brought before the notice of the Ophthalmological Society a new operation—viz., dissecting a flap from the cheek, drawing it through a buttonhole made in the eyelid, and attaching it to the raw surface of the lid.—THE LANCET Nov. 23rd, 1889.

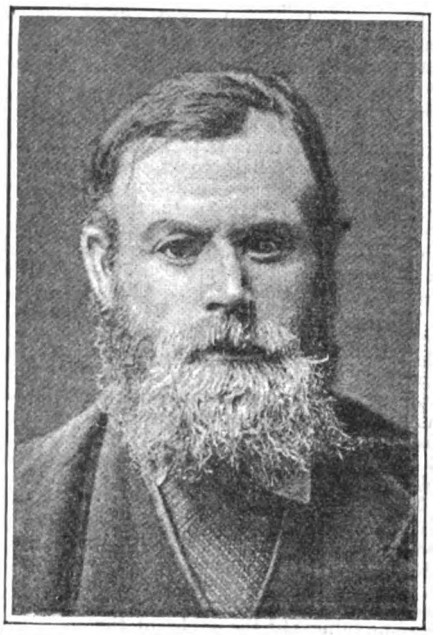
Digitized by Google



stitched in its new place. Both eyelids are closed with lint and a bandage, and kept so for four days. The ligatures are left in for six or eight days.

With regard to the patient, it must be borne in mind that it is a tedious operation, so that it is impracticable to administer chloroform. To young subjects I administer it only during the first stage—i.e., during the separation of the eyelid; for the remainder of the time moral suasion must be resorted to. In cases of grown-up people I generally perform the operation without anæsthetics.

The following case is very interesting, as it marks the transition from the old to the new method of procedure—symblepharon and anchyloblepharon (total) cured by transplantation from the rabbit (July, 1883).



Jeremiah J——, steelworker, aged twenty-two, got his left eye burned by a flash of slag from the forge hammer nine years ago. He was under treatment at Workington for four months, after which he was sent to the Manchester Eye Infirmary. Here (he states) attempts were made to keep the eyelids apart by means of strings and lead and a ring round his nose. When he came to the Glasgow Ophthalmic Institution, on March 17th, 1883, the eyelids were completely closed, the free borders of the lids were obliterated, so that the dissection of the upper and lower lids from the globe

FIG. 4.

was effected with great difficulty. "Buried under the lids" is an exact description of the state of the eye in this case. When the lids had been dissected, we found that only the upper and outer quadrant of the cornea was transparent; the rest was quite opaque. By means of ligatures inserted into them the lids were kept separate, and an artificial pupil was formed in front of the transparent cornea. The symblepharon was subsequently remedied by transplanting conjunctiva from the rabbit. The conjunctival sac is now free through its whole extent. The eye is movable in every direction; vision is restored. Fig. 4 is the photograph taken of the patient after the operation. This method of conjunctival transplantation has been practised successfully by Professor Otto Becker (Heidelberg), Professor Albrech Graefe (Halle), Professor de Wecker (Paris), and Marc Defour (Lausanne). Among American surgeons, Dr. Noyes (whose cases amounted to about a dozen) first applied this operation to the formation of the conjunctival sac for the purpose of fitting in an artificial eye, when the natural cavity had become contracted; but Professor Cohn of Breslau had previously performed the operation for the same purpose. There is one question, and that a most essential one—namely, as to the durability of the operation. It is satisfactory to make a conjunctival sac, but how long will it last? Do the surfaces by constant friction tend to adhere? We frequently have an opportunity of examining patients long after the operation, and have always found them satisfactory. This photograph (Fig. 5) of Peter C——, whom I exhibited at the Edinburgh meeting in 1875, was taken eight years after the operation, and in his

FIG. 5.

P. C—— is a remarkable patient. The injuries which he had sustained to both eyes and eyelids were extensive, so that I had to practise in his case several operations before his eyes were rendered serviceable and his face presentable. Left eye: 1, Artificial pupil; 2, conjunctival transplantation from the rabbit. Right eye: 1, Paracentesis for supposed hypopion; 2, skin-grafting on upper eyelid; 3, plastic operation on lower eyelid.

case the conjunctival sac is still as perfect as it was then. Both eyes are good. He has been all the time working at the quarries.

TWO CASES OF DIPHTHERIA.

A SUGGESTION AS TO TREATMENT.

BY W. TONGE-SMITH, M.D.

CASE 1.—This case seems a curiosity, and as such is worth recording. Florence H——, aged sixteen years; father a watchmaker. She was first seen on the evening of June 25th, 1884. She became so ill and weak about noon that she was unable to stand in the shop, and had to go to bed. She did not feel quite herself the previous evening, suffering from chilliness, headache, and nausea. These continued. She experienced severe frontal headache; expression dull and heavy; lumbar pain, extending up the right side to the shoulder; tongue large, flabby, and thickly furred; bowels confined; pain over abdomen on pressure; dysuria; "regular"; physical examination of chest &c. reveals *nil*; urine acid, sp. gr. 108; albumen one-third; pulse 126, not hard; temperature 101·6°; respiration 30. The patient was ordered slops, hot bath, and castor oil.—26th (morning): Bowels acted after the oil; felt more comfortable after the bath. Lumbar pain better, but headache worse; other symptoms the same. Now complains of severe sore-throat; has had it slightly for a day or so. Examination shows a dirty white membrane over both tonsils, back of pharynx, and edge of velum, cleaning from right tonsil, and on this side the glands are swollen and tender under jaw. No rash. Urine still albuminous. Temperature 101·4°; pulse 112. Has been staying at Hackney with a sister, who and whose children have had

Digitized by Google

sore-throats. Ordered lime-water spray, and internally sulpho-carbolate of lime. Evening: Pains gone; the throat the same. Temperature 102·6°; pulse 126.—27th (morning): Feels better; throat cleaning. Temperature 100·2°; pulse 100. Albumen one-sixth; no blood. Evening: Temperature 100·8°; pulse 100.—28th: Better, only weak; throat clean. Temperature 99·8°; pulse 98. A trace of albumen.—29th: Faint trace of albumen. Temperature 99°; pulse 91, not regular. Heart sounds normal.—30th: Stronger; no albumen. Temperature 98·4°; pulse 84, still slightly irregular. Tonics were prescribed. The patient now seemed convalescent, was recovering strength, and was placed at the window daily to inhale fresh air.—July 4th: Everything returned. Urine albuminous. Temperature 101·8°; pulse 100, irregularity more marked. Thick yellowish membrane, like an elongated half-crown, over both tonsils &c., terminating abruptly; tissues bordering it tumid and red. Spray &c. resumed. Evening: In the same condition. Temperature 102°; pulse 90.—5th (morning): Throat cleaning. Albumen present. Temperature 99°; pulse 70. Evening: Temperature 100·8°; pulse 70.—6th: Pieces of membrane at circumference only. Albumen gone. Temperature 99·8°; pulse 70.—7th: Better. No albumen. Throat clean. Temperature 99·4°; pulse 67, still irregular.—8th: Better in every way. No albumen. Temperature &c. normal; pulse the same. All went well, though strength was slowly gained. No sign of paralysis was ever noted, but the girl sometimes *thought* "food would return by the nose."

CASE 2.—J. H. A——, a short, slim lad of eight years and fair complexion, was admitted into the London Fever Hospital on Nov. 1st, 1882, having suffered from malaise and slight sore-throat for five or six days, and now complaining of increasing weakness. On the left tonsil was seen a white patch the size of a shilling, of fair consistence, quite adherent, and with a well-defined margin; surrounding tissues red and slightly swollen. There were pain, tenderness, and some fulness at the angles of the jaws, especially the left jaw. Tongue furred; bowels confined. Temperature only slightly raised. Pulse good, regular, and only slightly quickened; heart sounds normal. Respiration hurried, and accompanied by much hacking cough—both having well-marked laryngeal characters; air entering lungs very well. No cyanosis. He was ordered nourishing diet &c., and the chlorine spray.—4th: No membrane in throat; otherwise the same. Laryngeal symptoms still pronounced.—8th: Boy bright and cheerful, but stridor &c. worse. Has had three attacks of dyspnœa, a rather severe one last night at eleven o'clock, but it passed off and the lad slept peacefully. Albumen has appeared in the urine. Has been slightly sick. Ordered ten grains of ipecacuanha powder till sick.—9th: Sick after the first dose of ipecacuanha, but no membrane recognised in vomit. Passed a good night. 10 A.M.: Reported to have just "had a spasm; became blue, and almost choked." Found to be decidedly cyanotic and distressed; voice nearly gone; pulse rapid and feeble; boy mentally excited; air enters lungs badly—retraction; improved gradually. At about 10.30, another attack coming on, I immediately performed tracheotomy, a large quantity of membrane being coughed up. The boy improved at once, the pulse becoming slower, steady, and stronger. Flannels wrung out of hot water were laid over the tube, and lime-water was sprayed directly over the tube at short intervals.—10th: General state excellent. No cyanosis. No sign of heart failure. Lungs healthy; breathing easy; much membrane is coughed up; and a thick creamy discharge exudes constantly from the wound and is coughed up.—12th: After this no more membrane as such was brought up, but the creamy discharge was most copious.—16th: Discharge less and much thinner.—17th: Discharge little and watery. Some cough still and laryngeal voice. Tube removed; comfortable without it. Spray left off. Tonics ordered.—20th: No albumen; no sign of paralysis. Wound healthy. Got up. Towards the end of December the boy was discharged well, the wound being quite healed and represented by a scar three-quarters of an inch long by a quarter of an inch broad. This case is recorded to direct attention to what seems to me to be a solvent action of lime-water upon diphtheritic membrane. I now use the saccharated solution, and alternate it with an antiseptic. Out of twenty cases so treated I have only lost one, and that due clearly to heart failure. I would also draw attention to the simplicity and efficiency of covering the tube lightly with a layer of flannel wrung out of hot water and frequently changed, thus avoiding scalding, damp bed, and other evils of tents and kettles. Some antiseptic also may be dropped on the flannel.

Warkton, Kettering.

ON TWO RAPIDLY FATAL CASES OF DIPHTHERITIC PARALYSIS.

BY F. FOORD CAIGER, M.D.LOND., D.P.H. CAMB.

THE fact that the great majority of cases of diphtheritic paralysis end in complete recovery has an undoubted tendency to make one under-estimate the danger which may underlie even the most trivial instance of the disorder. The following two rapidly fatal cases have served to emphasise this fact in my mind.

C. R——, a gardener, aged twenty-five, was attacked on May 22nd with ordinary pharyngeal diphtheria. There was nothing noteworthy in the attack except that the membrane was somewhat unduly persistent, the tonsils not clearing till the thirteenth day. His temperature reached the normal on the ninth day. There was no albuminuria and but slight glandular implication, nor was the illness followed by undue prostration. After a few days in the country he resumed his employment.

On July 1st, having finished his day's work, he again presented himself, saying that he felt very unwell. The man was so obviously ill that he was at once readmitted to the hospital. According to his account he had never felt really strong or well since the illness. About six days previously he began to have difficulty in speaking plainly, and afterwards noticed that there was increasing difficulty in swallowing, the food often getting into the air passages or returning through the nose, with frequent fits of choking. Had felt numbness in the fingers and feet for the last two days, but was able to do his work, though greatly fatigued thereby. When admitted, at 6.30 P.M., it was extremely difficult to understand what he said, phonation being very imperfect and the voice hoarse and nasal. There was great difficulty in swallowing either liquids or solids, frequent shallow hoarse cough, with inability to clear his fauces. The vocal cords were seen to be lying in the cadaveric position, and moved but slightly towards the mid-line. The larynx was anæsthetic. Muscular power in arms weak, and tingling in feet. Patellar reflex *exaggerated*. Temperature 103 6°; respiration 40, shallow and jerky. Pulse 120.—2nd: Passed a restless night. Complete inability to swallow; fed with soft stomach-tube. Voice inaudible. Repiration 48, shallow and noisy. Diaphragm acting very feebly, if at all. Face dusky, sweating. Pulse 120, regular. Patellar reflex *absent*. Analgesia in legs, but can feel cutaneous pressure. During the afternoon the sweating continued; cyanosis became more marked. Pupils dilated. Respiration over 50, very shallow. Died quietly at 5.45 P.M. Twenty-four hours before his death the man was at work.

The second case occurred in a child aged five years. C. D——, admitted on Aug. 28th with faucial diphtheria, complained of sore-throat and vomited the day before. The case was a severe one, characterised by abundance of exudation on tonsils and pharynx, much glandular swelling, rhinorrhœa, and great prostration. On Sept. 6th he had a severe syncopic attack, but rallied under stimulants. The membrane in this case, too, was very persistent, the throat not becoming free until the sixteenth day. The temperature reached the normal on the eighth day, and afterwards was usually subnormal. There was slight albuminuria from the first, which remained as a nearly constant trace throughout the illness. With the exception of some paralysis and loss of reflex in the palate and a certain amount of glandular swelling, the ensuing convalescence presented nothing unusual. On the 17th it was noted that the voice had quite lost its nasal tone. On the 20th the patellar reflex disappeared; the palate was anæsthetic. No motor paralysis observed. On October 2nd food was noticed to return through the nose. Palate immovable; no reflex. Bilateral ophthalmoplegia externa especially affecting the right internal rectus, which was quite paralysed. Accommodation sluggish; irides react to light. Walk very "groggy"; patellar reflex absent.—14th: Double ptosis, most marked on the left side. Albuminuria slight; child sitting up in bed playing with its toys.—

Digitized by Google

15th: Inability to swallow; voice indistinct; dyspnœa. Ocular paralysis complete. The legs and back appear very weak; cannot support himself in a sitting posture. No resistance to passing the stomach tube. Diaphragm not acting; thoracic respiration feeble (40 to the minute); inability to cough; restless and sweating; pulse 100, regular. Towards evening cyanosis became marked. Temperature 99·8°; respiration over 50, shallow and noisy. Died at 11 P.M., the pulse being perceptible for some time after respiration had ceased.

It is remarkable that in both instances, although paretic symptoms were present for about a week before death, yet it was only within the last thirty-six hours that the cases took on a serious aspect and proved fatal by respiratory paralysis. The symptoms pointing to an affection of the vital functions occurred during the late stage of convalescence—viz., in the fifth and sixth week,—a time when it is more usual to find a form of paralysis mainly characterised by an affection of the spinal nerves supplying the limbs. In both cases the faucial affection was severe, the membrane being very persistent. This is in accord with my own experience—viz., that it is the severe cases which are most frequently followed by subsequent paralysis, the mild ones usually escaping altogether. I believe that in a good many cases of paralysis which are diagnosed to be of diphtheritic origin the original attack of diphtheria is accepted on insufficient evidence; the statement elicited from the patient or his friends that he has had a sore-throat some weeks previously (in one case I remember it was three months) being taken as sufficiently conclusive evidence that it was an attack of diphtheria, whereas the case might with equal propriety be referred to the operation of some other cause of which we are ignorant. Cases of peripheral neuritis of alcoholic origin may be the type of a wider series, and they certainly bear a close clinical analogy to diphtheritic paralysis.

I have been repeatedly struck by the fact that those cases of diphtheria which during the acute stage present a large amount of mucoid secretion at the back of the pharynx, accompanied with rhinorrhœa, are of the most grave kind, and rapidly reach a fatal termination. The increased secretion, however, is probably only apparent, the accumulation being due to retention, and is a sign of the oncoming paralysis of deglutition, which quickly becomes associated with laryngeal affection and cardiac or respiratory failure. It is this paralysis of early onset, affecting as it does the vital functions, which is so frequently fatal, and tends, I think, to support the view, adopted by Hilton Fagge on the theory of a "neuritis migrans," that there is direct association between the local process and an affection of the nuclei of origin or of the nerve trunks emanating from the medulla and floor of the fourth ventricle, from some of the peripheral fibres of which the diseased surface derives its innervation.

Fever Hospital, Hampstead.

CASES OF LITHOLAPAXY IN CHILDREN.

By LEWIS W. MARSHALL, M.D.,
SURGEON TO THE CHILDREN'S HOSPITAL, NOTTINGHAM.

THE following list of cases occurring in my practice may prove of service as an addition to those already published by others. The cases are taken in the order of their occurrence. The earlier operations were done at a time when it was extremely difficult to obtain lithotrites of the size required, owing to the great demand for them. As a result, some operations were ultimately completed by lateral lithotomy.

CASE 1.—W. H. W——, aged three years, was admitted on Nov. 12th, 1887. The calculus was measured (?) by palpation, and believed to be about the size of the last phalanx of the index finger.—20th: Chloroform given. No. 5 lithotrite introduced, but considerable time was lost in endeavouring to catch the stone; twenty-seven grains only removed by one crushing. The boy being a good deal collapsed, it was deemed wiser to send him back to bed. Some bloody urine was passed, and the temperature rose for a day or two afterwards. Much more pain and straining.—28th: Chloroform again given. The same lithotrite introduced twice; also a No. 6 evacuator. Four ounces of warm boracic lotion were injected before the introduction of the lithotrite. The buttocks were much more raised. This operation took forty minutes. The patient was sounded afterwards, but no piece was felt.—30th: Got up, but had a slight rise in temperature afterwards.—Dec. 20th: Went home.—July 25th, 1888: Readmitted with stone symptoms.—Aug. 24th: Chloroform given, and a calculus was felt and crushed by a No. 5 lithotrite after two introductions. Operation lasted fifty minutes; sixty-four grains removed.—28th: Got up, having been quite free from pain or symptoms since the crushing.—Sept. 1st: Discharged cured.

CASE 2.—W. H——, ten years of age, was admitted on Dec. 17th, 1887, with a history of "stone" symptoms for three months. On Jan. 1st, 1888, a No. 6 lithotrite was passed, and the stone was readily caught. The calculus was then found to be larger than had been previously estimated. The lithotrite strained in attempting to "crush," and was withdrawn with some trouble. A No. 10 evacuator had previously been introduced after slitting the urethra. No further attempt was made on this occasion, because the only lithotrite in hand was rendered useless.—8th: A No. 10 lithotrite was lent by Messrs. Weiss, and attempts made to introduce it. This failed. Lateral lithotomy was therefore done. The stone was found in two halves; it weighed five drachms, and was very hard. This case did very well, and remains so.

CASE 3.—H. S——, aged two years and a half, was admitted on May 19th, 1888, with a history of symptoms for two months.—28th: Sounded under chloroform, and stone gauged by palpation to be round and about the size of a hazel-nut.—29th: Chloroform given. A No. 6 evacuator passed; two ounces and a half of warm boracic lotion were injected into the bladder after withdrawing the urine. A No. 5 lithotrite was introduced, and the stone easily caught; it was soft and easily crushed, and almost entirely removed by the first introduction of the evacuator. The lithotrite was passed a second time and a small piece pulverised and afterwards removed by the same evacuator.—31st: Got up and was quite well.

CASE 4.—G. A. G——, aged four years, was admitted on June 2nd, 1888, with a history of three months' pain.—17th: The stone measured by palpation and believed to be about the length of the last phalanx of the index finger.—21st: Chloroform. A No. 9 evacuator was passed the first time. A No. 5 lithotrite was passed, but the stone being found to be hard and larger than was expected, an old French lithotrite (the only one available) replaced it. A smaller evacuator had to be introduced on account of the swelling of the urethra. The boy became collapsed after the removal of 97 grains.—Aug. 24th: Lateral lithotomy done, and the remainder of the calculus removed; it weighed 226 grains, the sum total being 323 grains. The boy recovered quickly.

CASE 5.—E. C——, aged two years and ten months, was admitted on Oct. 27th, 1888. He had always had difficulty in passing his urine.—Oct. 28th: Meatus found to be very small; enlarged, therefore, under cocaine.—30th: The symptoms being unrelieved, a sound was passed. A calculus was found and described in the following words—viz., "Flat, ovoid, and about an inch in length." This opinion was formed by palpation.—Nov. 11th: Chloroform was administered. A No. 5 lithotrite could not be passed after slitting up the urethra still further. Lateral lithotomy was performed, and the boy did well. The calculus was found to be three-quarters of an inch long, ovoid, and with flattened surfaces.

CASE 6.—H. W——, aged eight years, was admitted on March 27th, 1889. Pain &c. for two years. The calculus was measured by palpation, and described as flat, ovoid, and about an inch in size.—April 8th: A No. 9 evacuator was passed, and a No. 8 lithotrite afterwards. Boracic lotion was injected. Two crushings only were performed. The time occupied was thirty-seven minutes. Weight sixty-seven grains.—Nov. 11th: The boy sat up in bed; he had passed a few pieces the day after the operation.—13th: Was riding a rocking-horse in the ward.

CASE 7.—G. W——, aged seven years, was admitted on Aug. 7th, 1889. Pain for one month only. The patient was sounded and stone felt to be "light and small."—14th: Chloroform was given and the urethra slit up. A No. 8 evacuator was introduced to inject boracic lotion. A No. 8 lithotrite was passed, and crushing completed in seven minutes. A No. 10 evacuator was introduced, and the whole stone removed; it weighed one scruple. The time occupied in performing the operation was twenty-seven minutes.—16th: Got out of bed.—17th: Discharged cured.

Digitized by Google

CASE 8.—A. J——, aged seven years, was admitted on Aug. 14th, 1889, giving a history of an injury to the perineum two years before; painful micturition since then. Catheter passed and a calculus found; urethra sufficiently large to admit a No. 7 catheter.—18th: Chloroform. Stone gauged to be about the size of a hazel-nut. A No. 8 evacuator passed and the bladder injected. A No. 8 lithotrite introduced, and first crushing occupied twelve minutes. A No. 5 lithotrite afterwards used to complete the crushing. The whole operation occupied thirty minutes. The stone was hard and crushed at first with some difficulty; it weighed forty grains.—19th: Passed a small piece during the night.—20th: Discharged cured.

Remarks.—I have published this entire list of cases because they record fully my first attempts to do litholapaxy. They emphasise the rule laid down by those who have had much experience in this operation in children, that it is essential the surgeon should be well supplied with lithotrites. Happily now we need have no difficulty about this. It is also made clear that the measurement of the stone by palpation is not easy at first. Lithotomy, whether supra-pubic or lateral, is likely to be much less frequently done than in the past.

Nottingham.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

CARBOLIC ACID IN TYPHOID FEVER.

BY E. ATHERDEN THOMPSON, L.R.C.P., M.R.C.S.

THE following case may be of interest as evidence of the abortive power which has been ascribed to carbolic acid in typhoid fever. The patient, a young man aged twenty-one, lived in a house at which I had, during the early part of the present year, attended two consecutive cases of this disease. On being summoned I elicited a history of well-marked premonitory symptoms, including pains in the back and limbs, severe headache, lassitude, anorexia, vomiting, and rigors. On physical examination I found tenderness on pressure in the right iliac region, accompanied by gurgling and tympanites. Temperature 103·4°, pulse 95, tongue furred, patient apathetic and drowsy. I ordered the usual strict dieting, and prescribed a mixture containing minim doses of carbolic acid and two grains of quinine to be taken every four hours. On the second day of attendance I found the patient much better. Temperature subnormal; bowels, which had been somewhat constipated, relieved by a single foul liquid motion; no aperient had been given. For the following three days the temperature continued to be subnormal, although I had discontinued the quinine; it then gradually approached the normal, and never again rose above it. Beyond the appearance, on the fourth day of attendance, of a few somewhat equivocal rose-coloured spots on the back and abdomen, the characteristic eruption was not developed. By the seventh day all symptoms had disappeared, with the exception of occasional pain and a little tenderness on pressure in the iliac region. Taking together the well-marked premonitory symptoms, the condition of the patient when first seen, and the fact of two cases having previously occurred in the same house, I think I was justified in diagnosing typhoid fever, and in attributing its arrest and cure to the administration of carbolic acid.

Kirkham, Lancashire.

EXTRA-PERITONEAL FAT SIMULATING HERNIA.

BY W. THELWALL THOMAS, L.R.C.P. ED., &c.

THE following condition was met with in the anatomy rooms a few days ago, and appears of interest surgically. A well-developed male body was noticed to have a small swelling above Poupart's ligament on the right side, which could not be diminished by pressure, and was apparently in the inguinal canal. On removing skin and fascia the bulging was more pronounced, and was now seen to be entirely in the inguinal canal; on opening which a rounded portion of fatty tissue was found lying on the spermatic cord, which was flattened to accommodate it. The mass was polypoid in shape, about two inches long and an inch and a half across its free extremity; the neck could only be seen on drawing it down from the abdomen; the fat was very soft, and on its posterior aspect a thin fibrous cord was formed, but no covering as of peritoneum existed. On examining the interior of the abdomen, a short omentum was found, and perfectly free. The peritoneum over the inguinal region was without pouching; therefore the fat was certainly not omental. In this region and on each side of the pelvis there were well-marked eminences, due to enlargement of portions of the extra-peritoneal fat; and on making a section into the inguinal canal, the mass of fat discovered here was continuous with, and part of, one of these enlargements. One can imagine how such a condition so marked as to give rise to a distinct swelling externally would undoubtedly have been "cut down upon" if any symptoms of intestinal obstruction had manifested themselves. In fact, the appearance was one of well-marked bubonocele.

Liverpool.

DEATH THROUGH IMPACTION OF A PEA IN THE BRONCHUS.

BY E. F. GRÜN, M.R.C.S., L.R.C.P.

ON Oct. 25th M. D——, a child aged two years, was playing with some peas, three of which she placed in her mouth. A fit of coughing took place, and one pea was missed. Whether the child had swallowed the pea or not was uncertain. Air entered freely into both lungs and there was no dyspnœa. For a period of four weeks the child continued in fair health, but died suddenly in her cot on Nov. 28th. At the post-mortem examination a pea, soft and swollen, was found in the trachea at its bifurcation. It had evidently been impacted at the commencement of the left bronchus. The left lung was solid and fibrous; there was a good deal of mucus in the tubes, but no breaking down of lung tissue. At the apex there was considerable emphysema, and at the base adhesions of the pleura to the diaphragm and chest wall. The right lung was perfectly healthy. Other organs all quite healthy. The question is, could anything have been done to save the child's life if it had been possible to diagnose the presence of the pea in the right bronchus? In this clinical experiment, accidentally brought about, it is interesting to note that the result of impaction and occlusion of the bronchus was to produce emphysema and also pleuritic adhesion, with a general increase of fibrous tissue throughout the lung, but with no inflammation or actual destruction of lung tissue. Death, I believe, was caused by the pea becoming dislodged and occluding the right bronchus, thus producing instant suffocation.

Putney, S.W.

A CASE OF OLD UNREDUCED DISLOCATION OF HIP.

BY G. MICHELMORE, M.R.C.S., &c.

THE following may be cited as showing the irreparable damage done by neglecting to obtain advice in surgical cases. A. B——, a fine healthy girl ten years of age, was brought by her mother to the out-patient department of the infirmary, on account of the right leg being very much shorter than the left, which was causing the child some inconvenience in walking. The history of the case was that the child had a fall from its cradle in infancy, and a short time after the accident the mother noticed that the right leg did not appear to be of the same length as its fellow, but took no further notice of it. On making an examination, I found a well-marked dislocation of the right hip backwards on to the dorsum ilii. The head of the femur had accommodated itself wonderfully well in its new position, and the movements of the limb were free and easy, especially flexion and extension; but on comparing measurements with the sound side, I found a shortening of two inches and a half. Considering the number of years that had elapsed since the accident, and the changes that must have taken place in the acetabular cavity, no attempt at reduction was made.

ST. THOMAS'S HOSPITAL.

A CASE OF POISONING BY FOUSEL OIL; RECOVERY; REMARKS.

(Under the care of Dr. ORD.)

LITTLE has hitherto been known of the poisonous effects of fousel oil or, as it is also called, oil of grain and potato spirit, and the following account is a most important contribution to toxicology, for no accurate record of an undoubted case is known. A child on two occasions became partially comatose, and had livid lips and a feeble pulse after eating some confectionery, which, it was calculated, contained one drop of the essence used to give the flavour of the Jargonelle pear to it.[1] Experiments on animals has led to the conclusion that fousel oil is a powerful poison, especially if breathed in the state of vapour.[2] Guy and Ferrier[3] state that it acts as an inebriant, whether swallowed or inhaled, causing headache, giddiness, and staggering gait. Its toxic effects on man are said to be more powerful when taken in the state of vapour than when taken into the stomach, and it is interesting to note the effect of the fumes exhaled from the patient on those in attendance. Another point of note is the penetrating odour of the fumes, which filled the large ward in which the patient was placed, making it smell of bad spirit for some days. A condition somewhat similar to that described below, and due to the action of naphtha, is to be found in our columns. A boy, twelve years of age, took about three ounces of naphtha, became insensible with a sallow and clammy skin, followed by complete muscular relaxation, with a fixed state of the eyes and progressive difficulty in breathing, ending in death within three hours, although vigorous treatment was employed.[4] For the following report we are indebted to Mr. T. P. Cowen, house-physician.

T. S——, aged sixty-four, a coal-porter, was admitted to George ward, St. Thomas's Hospital, on Oct. 31st, 1889, under the care of Dr. Ord. At 5.30 A.M. on Oct. 31st the patient entered a public-house and ordered some beer. While drinking this he noticed under a seat a small champagne bottle which was full of some spirituous liquor; liking the smell of this, he drank several times from the bottle, taking about half a quartern each time (amount as estimated afterwards quite half a pint). He felt no ill effects, and resumed work until 10 A.M., when he became unconscious. He was brought to the hospital at 12.30 P.M., being quite unconscious; lying on his back, the muscles of the arms and legs were somewhat rigidly fixed in an extended position; the muscles of the neck and back but slightly rigid; there was no arching of the back; the teeth were tightly clenched; his face bluish; breathing shallow and infrequent; the pulse could only just be detected at the wrist. The pupils were small, and acted feebly to light; the conjunctival reflex was absent. The surface of the body was cold. No knee-jerks could be obtained owing to the rigidity of the muscles. His breath had a peculiar odour, something like that of nitrite of amyl or that of pear-drops. A stomach-tube was passed, and the stomach washed out, a quantity of a clear liquid being removed by so doing; this was colourless, and had a peculiar strong alcoholic smell. The patient remained in the same comatose condition, breathing fairly well, until about half an hour after admission, when the breathing began to become more and more shallow and slow, and the face and the ears more cyanosed, and he ceased breathing within the next few minutes altogether, although the heart was beating fairly well. Artificial respiration was begun, and kept up for quite five minutes before the breathing by natural efforts was resumed. During this time his body became more limp and the pupils larger; this failure and finally stoppage of respiration occurred several times between 1.15 P.M. and 2 P.M., and artificial respiration was kept up during the greater part of this time. At 1.45 P.M. twenty minims of ether were injected hypodermically; one ounce of brandy by the rectum. Shortly after 2 P.M. the breathing became much deeper and more regular; while the face, although still bluish, had more of its natural colour; the pulse could be felt easily at the wrist, the pupils were still larger, but only acted very sluggishly to light. He was still quite unconscious. Temperature 97·2° in axilla. The patient remained quite unconscious until 9 P.M., when he seemed to wake up, recognised his friends, and answered rationally, although he seemed very dull and dazed. Breath still smelt strongly of some spirit (like bad whisky) and of nitrite of amyl or the essence of the Jargonelle pear. Between 5 P.M. and 6 P.M. he vomited several times, the vomit consisting chiefly of mucus, but still smelling strongly of the spirit and of the "pear" odour. The urine drawn off by catheter at 4 P.M. was high-coloured, and had the same peculiar odour as the breath. He slept well during the night and sweated profusely, the sweat having the same peculiar odour as the breath. He did not again become unconscious or vomit, but passed the evacuations into the bed. There was no diarrhœa. The temperature at midnight was 98·8°; pulse 76, small and easily compressible.

Nov. 1st.—He is quite conscious this morning, but is still dull and heavy; he complains of a burning pain in the throat and stomach and of frontal headache. The fauces are reddened and swollen; there is no epigastric tenderness; face still bluish. The same peculiar odour in breath, but it cannot now be detected in the urine. Pupils widely dilated, and act well to light. Tongue furred; he has slight difficulty and pain in swallowing. Temperature normal; pulse 76, feeble. Arteries thickened.

2nd.—He has now lost all pain, and says he feels quite well; he sleeps heavily, and seems drowsy in the day time.

3rd.—He was discharged. Face and ears have still a bluish tinge. (This was not so before, according to the man's statement.) Breath has still the same smell, although it is much fainter.

He was a well-built man, looking much younger and healthier than one would expect at his age (sixty-four); and, considering his habits (he had been a heavy drinker, especially of spirits, for many years), all the organs of the body were apparently healthy. Urine acid, sp. gr. 1024, scanty in amount. No albumen or sugar. Knee-jerks brisk; superficial reflexes normal. The small champagne bottle from which the patient had drunk was brought to the hospital later in the day. It contained five ounces of a clear, colourless liquid, having a strong odour of amylic alcohol, and giving the characteristic reactions of that alcohol. The contents of the stomach had the same odour, and gave the same reactions. The total capacity of the bottle was fifteen ounces, and as it was full when the patient began to drink from it, he must have swallowed about half a pint. Dr. Bernays examined the liquid remaining in the bottle, and found that it was about half fousel oil and half spirit; sp. gr. 0·8406. It begins to boil at 89°; some distils over again at 94° and 113°, and a very considerable residue at 130°, the boiling point of fousel oil. It gives reactions of amylic and ethylic alcohols. Dr. Bernays also examined two specimens of urine, one drawn off by catheter four hours after admission, the other on the following day. Both specimens contained a small amount of ethylic alcohol and a minute though quite appreciable quantity of amylic alcohol; in both urea was much increased.

Remarks.—Certain of the features of this case are peculiar and interesting: (*a*) The long interval, quite four hours, between the time of ingestion of the poison and the development of symptoms. The man went on with his work as usual during this time; he felt no ill effects, nor did anyone near notice anything wrong with him until he suddenly became unconscious. The probable explanation of this is the long-continued habit of taking ardent spirits indulged in by the patient. (*b*) The marked effect on respiration. The blueness of the face, which although best marked shortly after admission and was then due in great measure to failure of respiration, lasted to some extent during the whole of the time of his stay in the hospital, and was still present when the patient went out. The pupils at

first contracted, and becoming larger as the patient recovered. (c) The peculiar odour in the breath (of nitrite of amyl or of the Jargonelle pear), which could hardly be detected in spirit itself, and which also lasted for days. Some chemical change must have occurred in the spirit after its absorption. The fumes of spirit exhaled from the patient caused in those attending him severe frontal headache, giddiness, and feelings of malaise, which lasted some hours.

LIVERPOOL NORTHERN HOSPITAL.

A CASE OF VARIX OF THE STOMACH; HÆMATEMESIS; DEATH; NECROPSY.

(Under the care of Dr. BARR.)

THE following case is one of an extremely rare condition of the stomach, of which we have been unable to find similar examples on record. Bristowe[1] remarks: "Dilated or varicose veins of internal organs no doubt occur, and aid in the production of functional disturbance; they may even rupture and cause death by hæmorrhage. We have witnessed this accident in the case of varicose veins of the œsophagus. But their presence can rarely, if ever, be recognised during life. The importance of the dilatation of certain groups of superficial veins in enabling us to judge of the seat and character of internal diseases involving the obstruction of deep-seated veins is obvious." Dilated veins in the mucous membrane of the stomach are sometimes met with as the result of portal obstruction. Passive congestion is of frequent occurrence, leading in many instances to hæmorrhage and as a result of that to hæmorrhagic erosions. The ulcers to which this term is applied are said to be most commonly placed at the lower curvature or near the pylorus. The clinical account of the case and the post-mortem description of the condition will be read with much interest. For the following account we are indebted to Mr. A. M. Barford, house physician.

P. H——, aged thirty, a dock labourer, was admitted into the hospital for the first time, under the care of Dr. Barr, on Nov. 21st, 1888. About five years previously the patient had an attack of acute nephritis, and since that time has been subject to mild attacks of the same, with slight dropsy. On admission he complained of shortness of breath and pain in the chest; he was pallid, and had a flabby appearance; there was slight œdema of the lower extremities, and the eyelids became swollen in the early morning; he complained of considerable frontal headache; the urine on some days contained albumen, on other days was free; specific gravity 1012, acid. These, shortly, were the symptoms on admission. He remained in the hospital for about a month, and, having considerably improved, was discharged.

He was readmitted on Jan. 2nd, 1889, complaining of great dyspnœa and pain in the chest. He was very anæmic, and remained in the hospital, improving considerably, until Jan. 28th, when he had an attack of hæmatemesis, which stopped after the administration of ergotine and ice. The next day he had a very severe attack, vomiting about forty-two ounces of blood; there was also considerable melæna. There were not, neither had there been at any time, any other symptoms of gastric ulcer, nor any other gastric or hepatic disease at any time. A day or two after this the patient seemed fairly well, and had no more hæmatemesis for about a month, when it began again, and continued at intervals of from two to three days until his death on March 7th, 1889.

Necropsy.—The kidneys showed signs of chronic parenchymatous nephritis; the cardiac end of the stomach was firmly adherent to the spleen by old inflammatory adhesions. On the mucous surface of the stomach over the adhesions there was a large vein which was ruptured, but plugged with a thrombus. (This was evidently the source of the hæmorrhage.) There was no ulcer of the stomach, but the adhesions seemed to prevent the return of venous blood. The spleen was normal in size and appearance, with the exception of being very anæmic; capsule thickened and very firmly adherent for about two square inches to the cardiac end of the stomach. The other organs were anæmic, but otherwise natural.

[1] The Theory and Practice of Medicine, p. 541.

Remarks.—The profuse hæmorrhage which took place from a large vein without any ulceration of the stomach appeared to be due to the adhesions to the spleen obstructing the vein and preventing the free return of blood. There were no means of determining the cause of the adhesions. The intermittent character of the hæmorrhage was due to the plugging of the vessel, and as a thrombus got detached a fresh hæmorrhage took place.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Association of Heart Disease with Diseases of the Pelvic Viscera in Women.—Blood Tumours of Bone.

AN ordinary meeting of this Society was held on Dec. 10th, Sir Edward Sieveking, President, being in the chair.

Mr. ARTHUR E. NEVINS read a paper on the Frequent Association of Heart Disease, especially Mitral Stenosis, with Diseases of the Pelvic Viscera in Women. In this paper the author called attention to: 1. The frequency of the association between heart disease and lesions of the pelvic viscera in women. 2. The great predominance of mitral stenosis over all other cardiac lesions in such cases, and the fact that the symptoms were easily overlooked unless a thorough and careful examination of the circulatory system was undertaken, the patients generally suffering from pelvic troubles for some considerable time before any symptoms obviously referable to the cardiac lesion developed. 3. An attempt to classify the lesions of the pelvic viscera in relation to the frequency of their coincidence with heart disease. 4. The diagnostic importance in many cases of disease of the pelvic viscera, of a knowledge of the soundness, or otherwise, of the heart. The observations recorded referred to 552 consecutive cases admitted into the Hospital for Diseases of Women, Soho-square. Out of these cases 133 had been omitted as having no bearing on the subject in hand, some of them being cases of cancer of the breast, others of renal disease, and so on. Among the 419 remaining cases, 111 patients (= 26½ per cent.) were found to have symptoms of organic disease of the heart, and, with only one exception, it was always the mitral orifice and valve that was affected. Of these 111 cases, 93 (=84 per cent.) were suffering from mitral stenosis, 29 (=26 per cent.) from mitral regurgitation, and of these 11 (=10 per cent.) from mitral stenosis and regurgitation combined. In the above

Table of Diseases of the Pelvic Viscera noted among 419 Patients, arranged according to the frequency with which Co-existent Heart Disease was discovered.

Disease.	No. of cases.	Cases of			Heart disease.	
		Pure mitral stenosis.	Pure mitral regurgitation.	Mitral stenosis and regurgitation combined.	Totals.	Percentages.
Granular erosion of cervix uteri	33	12	3	3	18	55

table all the patients comprised in the series were classified according to the diseases from which they were suffering; the sequence of these groups of cases depended upon the percentage of heart disease discovered in each. In this table the same patient is often enumerated more than once, as, for instance, a patient suffering from chronic enlargement and inflammation of the womb, and also from granular erosion of the cervix, would appear under both these headings; the aggregate numbers, therefore, will be found to considerably exceed the total given above.—Dr. BARNES said that the paper was an illustration of the solidarity of the functions of the body, and of the absurdity of endeavouring to consider one organ apart from the rest. Referring to the cases mentioned by the author of the paper, he said it was often impossible to make out whether the pelvic or the cardiac disease were the primary, but he was inclined to think that in many cases he had seen the pelvic affection precede that of the heart.—Dr. POWELL observed that in cases of mitral disease one was accustomed to meet with congestion of various organs, and menorrhagia was a common symptom. Of the large number of cases quoted many probably had nothing to do with the mitral stenosis, but some might be attributed to the disordered circulation, such as granular erosion of the cervix, menorrhagia, and a certain proportion of the inflammatory affections. Of the total number of congestive uterine lesions referred to in the paper, nearly two out of three of them were found to be associated with heart lesion.—Dr. WILLIAM DUNCAN said that in many of the cases the occurrence of heart lesion could only have been mere coincidence; he did not believe that erosion of the cervix could be caused by mitral stenosis any more than laceration could, though he admitted that heart disease in women predisposed to hæmorrhage. He related an interesting case in which he had come to the conclusion that a diseased condition of the uterus had been brought about by serious aortic regurgitant disease. He was prepared to admit that in some cases of menorrhagia and inflammatory uterine affection the heart played an important part.—Dr. ROUTH said that it was important to note that the existence of a cardiac complication rendered these cases very difficult to cure, and that explained why gynæcologists found it necessary to keep some of their patients so long under treatment. Congestion was inevitable in some cases of heart disease, and a French observer had pointed out that whenever there was erosion of the cervix, the same condition obtained in the back of the pharynx.—Dr. HERMANN referred to the difficulty in diagnosing mitral stenosis with certainty; he regarded it as a rare affection. He suggested that in studying the question of the association between diseases of the heart and those of other parts, the subject should be approached on a broader basis. First, there should be found among women suffering from pelvic disorders what proportion of heart disease existed, and then in patients with cardiac mischief it should be ascertained what proportion of them suffered from pelvic complaints. He had observed in the majority of cases presenting venous congestion from any cause, that there was a diminution of the quantity and frequency of the menses; menorrhagia was present only in a few.—Dr. FREDERICK TAYLOR said that the diagnosis of mitral stenosis was extremely open to fallacy, and looking at the list of symptoms which had been detailed he failed to see on what grounds the evidence of stenosis rested. The lesion, however, was much commoner than Dr. Hermann seemed to believe. He wondered whether if one took a number of cases of mitral stenosis the proportion of patients suffering from pelvic trouble would be greater than in patients with any other disease.—Dr. SEYMOUR TAYLOR said he had been for some years studying the subject of the connexion between visceral disease and gross lesions of the heart. He mentioned a case in which a large prostate was associated with palpitation, and yet post mortem no sign of cardiac disease was found. Malignant disease of the uterus was often associated with gross lesions of the cardiac valves. He related an instance of violent cardiac palpitation which occurred in a woman who was the subject of ovarian tumour. It subsided after ovariotomy, and many years after was ascertained not to have returned. In another case violent palpitation was associated with floating kidney. He felt quite sure that there was some connexion between valvular and functional disease of the heart and disease of the viscera. He thought that with improved instruments of diagnosis the recognition of mitral stenosis was not so difficult now as it formerly was.—Mr. NEVINS, in reply, said that he had given his grounds for the diagnosis of mitral stenosis, but his main point was to emphasise the fact that these cases of uterine disease were associated with a certain group of cardiac symptoms; he had mentioned the symptoms which had occurred most frequently, and he left others to drawn their own inferences as to their signification. He, however, had carefully read Dr. Acland's paper on Mitral Stenosis, and the symptoms described there so exactly tallied with those he himself noticed that he felt justified in making a definite statement as to the cardiac condition. He thought there were evidences that the cardiac disease in many of the cases preceded the pelvic disorder. He did not wish to advance the view that in all these cases the heart disease caused the pelvic lesion, but he wanted to show that certain groups of these cases had a larger proportion of heart lesion than others. He pointed out the difficulty of deciding between early malignant disease and simple congestive inflammation, and said that in these cases it was a great assistance to know whether any heart lesion was present.

Mr. EDWARD ROUGHTON then read a paper on Blood Tumours (Angeiomata and Angeisarcomata) of Bone. His object was to elucidate the nature of those tumours, which were occasionally found in the interior of bones, and which on dissection were found to consist almost entirely of blood. These tumours had hitherto been considered to be always of a malignant nature. It was shown that, although some (perhaps most) of them were malignant, some were only semi-malignant, and others quite innocent in nature. This fact was illustrated by the following series of cases arranged in order of malignancy:—1. Max Oberst's case, a highly malignant endosteal sarcoma. 2. Dupuytren's case, arrested for seven years by tying the main artery of the limb. 3. Roux's case, permanently cured by tying the main artery. 4. Lagout's case, similar to the preceding. 5. The case of L. C—— (detailed in the paper), in which the growth was arrested by simple incision. 6. MacDonnell's case, cured by the pressure of an elastic stocking. It was argued that these tumours consisted essentially of blood-vessels which being imperfectly developed were unable to contain blood, and so burst and destroyed the tissue in which they were contained. The author thought that these blood-vessels were developed from the myeloid cells of red bone-marrow, and that the more embryonic they were the more malignant the tumour in which they were situated. In the innocent blood tumour of bone the vessels were more highly developed, but still too weak to contain blood. When the vessels attained sufficient maturity to admit of no extravasation, the tumour ceased to have the characters of a blood tumour, and was, in fact, a pure angeioma. Such tumours, although more common in other parts, had been several times met with in bones. With regard to the treatment of these tumours, it was suggested that they should be incised, and if found to contain little or no solid matter, allowed to granulate up. If after incision the tumour continued to grow, free removal of the diseased part should be practised.—Dr. MAGUIRE said that he had examined several cases of malignant tumour of bone, and three of these presented appearances of extreme vascularity and pulsation; so much so that they might be mistaken for aneurysm. He had been able to trace the development of sarcomatous tissue from the muscle fibre of the arterial wall. The more malignant the tumour the more rapidly would it become vascular, and the more likely were the vessels to give way. The fact that sarcomatous tissue was often found only at the edge of the blood tumour showed how difficult the diagnosis might be, and therefore it was unwise to trust to the information gained from a simple incision into these growths. The tumours were not confined to the endosteum, for one case he had observed was an extremely malignant instance of periosteal sarcoma which recurred later in the viscera.—Mr. HOLMES differed from the last speaker as to the value of incision, for he recommended cutting into the tumour, evacuating its contents, and then if no obviously sarcomatous tissue were found, giving the patient the benefit of the doubt. The cases originally described by French writers as aneurysm of bone were really, he thought, cases of endosteal and periosteal sarcoma, and he did not know of any safe means of distinguishing between the two.—Dr. MAPOTHER referred to a case of angioma of the centre of the tibia, which came under his notice thirty years ago, and which was still alive and well. He removed the growth by the actual cautery. There was a history of previous injury to the shin.—Mr. BARWELL said that two

Digitized by Google

diseases entirely different were being mixed up together. Under the name pulsating tumour of bone were included two separate affections, malignant and angeiomatous growths, the one consisting entirely of bloodvessels and the other of vascular sarcoma tissue.—Mr. W. HAWARD referred to some excellent specimens of myeloid sarcoma in St. George's Hospital Museum; the bloodvessels were numerous and the tumours contained large cavities filled with clot. With regard to ordinary blood cysts, he imagined that they were the same in bone as elsewhere, the wall often being formed of sarcoma tissue, while a blood extravasation occupied the centre of the growth. Myeloid tumours differed greatly in their degree of malignancy.—Mr. ROUGHTON, in reply, said he had not been fortunate enough to watch the transformation of vessel wall into sarcoma tissue. The case of blood tumour of bone treated three years ago by incision was now in perfect health, and there had been no sign of recurrence. All the cases that he had been able to refer to were distinctly endosteal and not periosteal. Alluding to Mr. Barwell's contention that these cases were divisible into two distinct classes, the object of his paper was to show that there was every grade, from the most malignant to the perfectly innocent vascular bone tumour, just as there was in the case of fibroma, fibro-sarcoma, and sarcoma of the most malignant type.

MEDICAL SOCIETY OF LONDON.

Aneurysm of the Aorta.

A MEETING of this Society was held on Dec. 9th, the President, Dr. Theodore Williams, in the chair.

Dr. POWELL introduced a discussion on Aneurysm of the Aorta. He said that the object held in view was to elicit the experience of Fellows in the diagnosis and treatment of aneurysm. It was especially urged that the true clinical features of aneurysm were alone—with very rare exceptions—yielded by the sacculated form of the disease, and that both in regard to prognosis and treatment the so-called fusiform aneurysm was totally different. The aneurysmal sac was necessarily an enlarging tumour, producing—(1) pressure phenomena, (2) cardio-vascular phenomena. In enlargement of the vessel without sacculation pressure phenomena were insignificant or absent, the cardio-vascular phenomena very marked. Pressure signs were of the first importance in the diagnosis of aneurysm, and to imperfect recognition of this fact and the attachment of too great a value to circulatory phenomena were attributable most errors in diagnosis. He referred to the significance of bruit—systolic—diastolic; of thrill; of impulse perceptible to hand, to ear, and of diastolic impulse or jog. Cases of spurious thoracic and abdominal aneurysm were related, illustrative of some of the above propositions; also cases illustrating diagnosis of obscure sacculated aneurysm. The value of the laryngoscope as an aid in diagnosis, and of the sphygmograph as a recording instrument, were emphasised. The various methods were fully discussed. Dr. Powell's remarks will be published in full in a future number.

Dr. BROADBENT said that, with regard to the pressure signs and evidences of disturbances of the circulation, he agreed with the author that the former were more important for diagnostic purposes, with this qualification, that the pressure signs depended very much upon the situation of the aneurysm. In aneurysm of the ascending aorta the tumour might attain a considerable size and yet produce very little pressure upon neighbouring parts, owing to the natural mobility of the vessels; so much so that he was sometimes in the habit of speaking of this form as "the aneurysm of physical signs," while aneurysm of the arch proper or of the descending part was rather "an aneurysm of symptoms." He said that to hear a murmur was rather the exception than the rule. One of the most valuable signs independently of this was the "diastolic shock," either audible or perceptible to the hand. Passing on to the question of treatment, he agreed that fusiform aneurysm was not amenable to any treatment; the only thing was to lower the general intra-arterial pressure, enjoining rest if otherwise necessary, but not with the idea of promoting anything like a cure. He had nothing to add with respect to the Tufnell treatment, but his own experience with the iodide of potassium was that it very strikingly promoted consolidation within the sac. He mentioned an instance which came under his notice a long time ago when house physician to St. Mary's Hospital; in that case rest and dieting had been carried out very carefully for months without any result, but consolidation took place rapidly when iodide of potassium was administered. That was an experience which had been many times repeated under his observation. He observed that the health of the patient would not permit of large doses of iodide of potassium during the Tufnell treatment. His explanation of the action of iodide of potassium was that it virtually effected the same thing as the Tufnell treatment, running off the fluid by the kidneys, and so inspissating the blood. He mentioned the case of a woman who had remained in St. Mary's Hospital upwards of two years; iodide of potassium had been tried in the firs instance without effect, and they were reduced to watching the aneurysm gradually increase in size. Later on it occurred to him that the cases in which iodide of potassium did the greatest good were those in which there was a large sac with a small mouth, and he decided once more to give the iodide a trial, this time with complete success. He concurred in Dr. Powell's views as to the use of iron wire, but with regard to galvano-puncture he related an interesting case of left subclavian aneurysm in which consolidation had been twice effected by this means; but on both occasions the clot had subsequently broken down. The aneurysm was ultimately completely cured by pressure with a shot-bag. He only resorted to bleeding when there was pain, but the relief was then very striking. Alluding to Dr. Sibson's plan of treatment by use of ergot, it unquestionably diminished the size of the tumour, though this was certainly not due to any specific action on muscular fibre in the sac wall, since he had never been able to discover any there.

Dr. ORD mentioned that he had read a paper on this subject before the Society some years ago. He said that in a certain number of cases of aneurysm of the thoracic aorta the first indications were from the circulation. He insisted on the diagnostic value of local signs: pulsation, murmur, thrill, shock, dulness, undue pulsation, &c., relying on the pressure symptoms to complete the diagnosis. He pointed out the liability to error in cases where the lung was withdrawn from the front of the vessels, giving rise to pulsation and thrill; also in cases where tumour intervened between the aorta and the chest-wall. He mentioned cases in which the diagnosis had been rendered difficult in this way. He agreed with Dr. Powell in what he said in reference to the presence of murmur; as to the relative importance of sacculated and fusiform aneurysm; and as to the diagnostic value of the "diastolic shock," whatever its explanation might be; he contended, however, that it could be heard as well with a flexible as with a solid stethoscope. He agreed that the diagnosis of abdominal aneurysm was often very difficult, but he said that in most cases by careful palpation it was possible to determine whether the aorta was pulsating in its whole length, and, in the case of a localised tumour, whether or not it was expansile. With reference to treatment, he had found Tufnell's method very beneficial, but he generally associated it with iodide of potassium whether or not there was a history of syphilis. He mentioned the case of a patient of his who, seven years ago, had been treated for six months by means of the Tufnell treatment, and who had remained well ever since. He confirmed all that Dr. Broadbent had said with regard to the ergot treatment, and agreed in his explanation of the action of that drug. He especially called attention to the relief obtained in cases exhibiting pressure symptoms by the administration of ergot, of which he quoted several instances. The dose given by Dr. Sibson was twenty minims of the liquid extract with twenty drops of spirits of chloroform to cover the nauseating taste. His experience was that galvano-puncture did not necessarily give rise to central consolidation, and he referred to a case in which a post-mortem laminated collection of fibrinous matter half an inch thick was found on the walls of the sac; it was thickest where he had introduced the negative electrode.

Dr. BRISTOWE confined his remarks to treatment, as to which he said he was somewhat of a pessimist. He thought that drugs at most afforded a passing relief. His post-mortem experience seemed to point to the fact that the permanently cured cases—i.e., thoroughly filled up with clot—were cases in which aneurysm had not been suspected, and in which the patient had been bedridden and dying for weeks from something else. He admitted that that was rather in favour of the Tufnell treatment. He had no faith in treatment by wire or by galvano-puncture. In regard

Digitized by Google

to the case mentioned in which galvano-puncture had apparently inaugurated a cure, he did not think that there was sufficient evidence post mortem that the aneurysm was in course of cure. He had no faith in the iodide of potassium treatment, and though the drug had been administered to his patients by his house physicians, he had never witnessed any decided benefit result from it. In the cases alluded to by Dr. Broadbent, in which consolidation was said to have taken place, he urged that, as no post-mortem had been made, there was no evidence as to the nature of the consolidation. He mentioned a case of large aneurysm of the ascending arch in which many methods of treatment, including that by iodide of potassium, had been tried, with the result of apparently causing consolidation; but when the patient died they found that the aneurysm did not contain any clot at all. He was unable to give any explanation of the diminution in size of the sac which had occurred. Patients with aneurysm were benefited by rest and diet, and generally by means which reduced the blood pressure. He suggested, however, that it was open to question as to how far it was worth while rendering these patients useless members of society for the sake of a problematical prolongation of life for a few weeks or months, and he thought, on the whole, that it was preferable to allow them to carry on their usual avocations, even if they died a little sooner. He alluded to the cases of Dr. Murchison and Dr. Hilton Fagge, both of whom, though they suspected they were suffering from aneurysm, continued to work to the last. Many persons went on with their work, and for many years retained their health in spite of the presence of an aneurysm. A man working at the Edinburgh Infirmary had been known to have aneurysm of the aorta for ten years, and a patient of his own had continued at work for three years, with occasional treatment with benefit when the symptoms were severe. He urged that these patients were happier than if they had remained in bed all that time. He observed that while in sacculated aneurysm the main object was to get a firm clot within the sac, in fusiform aneurysm it was quite otherwise, such a condition, if brought about, being distinctly prejudicial to the patient. The discussion was then adjourned till Monday next, Dec. 16th. The President explained that the meeting would be a "clinical evening," devoted to the exhibition of cases of aneurysm, many living examples of which had been promised.

OBSTETRICAL SOCIETY OF LONDON.

A MEETING of this Society was held on Dec. 4th, A. L. Galabin, M.D., President, in the chair.

Specimens.—Dr. W. DUNCAN: (1) Abscess of Ovary; Hæmatosalpinx and Pyosalpinx; Subperitoneal Myomata; (2) Hydrosalpinx; (3) Myoma of Uterus; Abscess of Ovary. Dr. J. PHILLIPS: Distended Tubes; Hæmatoliths from Ovarian Cyst. Dr. AUST LAWRENCE: Sponge Tents. Mr. J. BLAND SUTTON: (1) Lock of Hair, thirty inches long, from a Dermoid Cyst; (2) Dermoid of Ovary, showing immunity of the Paroöphoron; (3) Ovarian Cyst, partly Adenoma and partly Dermoid; (4) Tubo-ovarian Cyst.

A Case of Inversio Uteri; Reduction; Recovery.—Dr. BRAXTON HICKS read notes of a case where a primipara aged twenty-six was delivered, as it seemed, at the time naturally. Free hæmorrhage followed, the placenta came away without assistance, and the patient did well till the third day, when, during an attempt at micturition, something came down and appeared externally. Efforts to reduce the mass, which proved to be an inverted uterus, by simple manual pressure proved unavailing, even under chloroform. The cervical portion was firmly contracted and resisted pressure. Dr. Hicks at length pressed a speculum with an obturator against the inverted fundus, which was thereby cupped. After steady gentle pressure the fundus could be felt gradually distending the cervical portion. The hand placed externally made counterpressure on the now enlarging ring of the cervix; at the end of ten minutes the greater part of the uterus was restored. The speculum was then withdrawn and the obturator from a larger speculum introduced, so as to give more room at the point of flexion. A minute later Dr. Hicks found the uterus in its normal condition. The first speculum and obturator were then introduced, and left for a few hours within the cavity, in order to prevent relapse. No bleeding occurred during or after reduction, and the patient made a good recovery. Dr. Hicks dwelt upon the opinions of Drs. M'Clintock, Aveling, Lusk, and Barnes. He gave full reasons why in this case fundal reposition, condemned by many authorities, proved successful when carried out in the manner indicated in his paper.—Dr. HORROCKS asked if the uterus was completely inverted, or whether a small portion of the cervix remained in place. If completely inverted, the "fundal method" of replacement might be better than the other, and there would not be the same objection to the method, because the thickness passing through the inverted os would not be greater than in the ordinary method of restoring the uterus.—Dr. W. S. A. GRIFFITH noticed that the case was reported as "spontaneous" inversion. He asked if any Fellow of the Society had himself actually witnessed inversion of the uterus, occurring in connexion with the third stage of labour, under circumstances which could be called absolutely "spontaneous."

On Closure of the Ostium in Inflammation and Allied Diseases of the Fallopian Tube.—The author, Mr. ALBAN DORAN, in this communication dwelt on the frequency of closure of the ostium in salpingitis; but the obstruction is often temporary. Obstruction of the uterine end is due to swelling of the mucous membrane or to the development of "Chiari's bodies" from that membrane. Permanent closure of the tube is almost synonymous with closure of the ostium. Salpingitis and perimetritis are the causes of closure of the ostium. Three essential factors in relation to the subject are considered at length. 1. The nature of the ostium and its fimbriæ. 2. The nature and varieties of salpingitis, and also of perimetritis as far as it affects the tube. 3. The precise manner in which the ostium is closed in perimetritis and salpingitis. In adhesive perimetritis the fimbriæ of the tube are bound down by bands, which thus obstruct the ostium. In salpingitis the ostium is obstructed, incompletely at first, by the swelling of the mucous membrane which involves the fimbriæ; but permanently in bad cases by great infiltration of the submucous tissue and middle coat, which swell over the ostium and cover in the fimbriæ. The perimetritic and salpingitic varieties of closure of the ostium, often blended, were demonstrated by specimens and diagrams. The question of timely conservative operations on obstructed non-suppurating tubes was discussed. Dr. Skutsch's "salpingostomy," where a small piece of the tube is excised, appears to be a promising step in that direction.—Dr. HORROCKS noted how often orifices in the body were the seat of disease, the ostium was no exception. He thought that it must be difficult to distinguish salpingitic from perimetritic closure of the tube.—Dr. RUTHERFOORD noted the relation between certain tubo-ovarian cysts and chronic tubal disease, which Mr. Doran had already indicated in other monographs.—Mr. DORAN replied that two specimens exhibited that evening were very pure examples of perimetritic and salpingitic closure of the ostium respectively. He maintained his theory that tubo-ovarian cysts were often the result of cystic degeneration of uterine appendages after long-standing inflammation. He admitted, however, that tubo-ovarian cysts might be congenital malformations, in rare instances, as Dr. Griffith and Mr. Sutton had endeavoured to prove.

Notes of a case of Monstrosity.—These notes were read by Dr. H. C. HODGES of Watton, Herts. The patient was a primipara aged twenty-seven. There was a large quantity of liquor amnii, and when the membranes were ruptured the presentation was hard to diagnose. The face appeared to present, and a soft pedunculated tumour appeared to lie behind the frontal bone. The forceps would not hold. On delivering the head the tumour, evidently a brain-sac, was ruptured. The fœtus proved to be an anencephalous monster. The vertebral column appeared to be malformed, the coccyx curved backwards, forming a short tail bearing hair on its tough integumental covering. There was ectopia of the viscera. The fœtus was a female.

Notes of a case of Hæmatemesis in a Newly-born Infant.—This paper was also read by Mr. HODGES. The child was born at 5 A.M. on April 23rd, 1888, after a natural and easy labour. At 11 A.M. the physician was summoned in haste as the child "had hæmorrhage." The child was found blanched, with a very faint pulse; all the surrounding clothes were saturated with blood which the child had vomited. The child was put to the breast without result, and was troubled with constant hiccough. It was kept quiet and ten minims of hazeline were given every two

Digitized by Google

hours. At 5.30 P.M. a tablespoonful of blood-stained mucus was vomited, and later on a copious evacuation containing blood was passed. The case was complicated by serous discharge from the left ear, with subconjunctival hæmorrhage and internal strabismus of the left eye; but within a few days convalescence set in, and the child was perfectly free from all the described symptoms at the end of a month and has remained well ever since. Mr. Hodges dwelt on the recovery of the child after the loss of a large quantity of blood and on the value of hazeline. The discharge from the ear, strabismus, and also partial facial paralysis, which was noticed in the course of the case but which soon disappeared, all seemed to indicate injury to the base of the skull, perhaps actual fracture, involving laceration of blood-vessels. This, coupled with the bright colour of the blood, made it probable that hæmorrhage had arisen not in the stomach, but in the posterior part of the pharynx or its neighbourhood, the blood being swallowed and afterwards vomited. In a case described by West hæmorrhage occurred into the arachnoid, causing apoplexy. Other cases of hæmatemesis in the new-born child might have arisen from a similar cause.—Dr. W. S. A. GRIFFITH described a case where hæmorrhage from the vagina occurred in a new-born eight-months' child. Death occurred from an independent cause. The uterus and vagina were found full of blood. The opportunities for investigating the causes of hæmorrhages in infants were very scanty.—Dr. DAKIN believed that these hæmorrhages were an expression of a general condition which had been called "hæmophilia neonatorum." This condition, however, was not, strictly speaking, hæmophilia. It seldom or never set in before the fifth or sixth day; so that in Mr. Hodges' case, although the labour was easy, the cause of hæmorrhage was most likely traumatic.—Dr. DAKIN recalled a case of copious vomiting where the child was free from pallor. He discovered a fissure at the base of the mother's nipple. On attempting to draw the breast through a glass shield blood issued freely from the fissure. This possible source of blood should be borne in mind in similar cases.—Dr. HERBERT SPENCER believed in Mr. Hodges' theory, and had several times observed fractures of the base of the skull, causing hæmorrhage beneath the periosteum.—Dr. C. H. F. ROUTH, on the other hand, believed that the hæmorrhage was due to injury of the delicate buccal mucous membrane. He had seen bleeding from the mouth in two premature twins; the mother had encouraged them to suck. In cases of this kind the infant should be fed on raw beef juice or milk.

The PRESIDENT, in conclusion, notified that the next meeting would be held on Wednesday, January 8th, 1890.

HUNTERIAN SOCIETY.

Facial Hemiatrophy.—Atrophy of Tongue and Optic Discs, with Paralysis of Soft Palate and Larynx.—Multiple Exostoses.—Progressive Muscular Atrophy.—Idiopathic Tetanus.—Comminuted Fracture of Patella.—Xeroderma.—Pityriasis Pilaris.

THE meeting on Nov. 13th was a "clinical evening," Mr. Clement Lucas, F.R.C.S., President, being in the chair.

Dr. PORT showed a case of Facial Hemiatrophy in a girl aged seventeen years. The atrophy began at the age of eight, and was not entirely restricted to the face and head. A full and able description of the case (by Jessop and Browne) is to be found in the St. Bartholomew's Hospital Reports of 1882.

Dr. TURNER showed a girl aged five years with Atrophy of the Right Side of the Tongue, Paralysis of the Soft Palate and Larynx, causing difficulty in swallowing fluids and feebleness of cough, loss of power in the right arm, which was half an inch less in the girth of the forearm at the elbow than the left, and atrophy of both optic discs, advanced in the right eye, the sight of which was nearly lost. The symptoms dated from a series of right-sided epileptiform attacks, which commenced six weeks after an attack of scarlatina in February, 1888, and occurred daily for two months. At first there was general paralysis of all the limbs, which were all weak in August, 1888, when the child first came under observation at the North-Eastern Hospital for Children. Since then the legs and left arm had greatly improved, and the right arm also to some extent. The condition of the tongue was much the same in August, 1888, as at present. The knee-jerks were absent. There was no evidence of syphilitic inheritance in the family history, and it was thought that the symptoms were due to some specific meningeal lesion at the base of the brain involving the ninth and portion of the eighth cranial nerve on the right side. Reference was made to a case of hemiatrophy of the tongue shown at the Clinical Society by Dr. Thomas Barlow, and recorded in vol. xxii. of the Transactions.

Mr. POLLOCK showed (for the President) a child aged fourteen years, with Multiple Exostoses. They were over forty in number, mostly situated about the ends of the long bones, but not confined to them. Those in the lower extremities were noticed soon after birth, in the upper extremities about three months ago.

Mr. MACILWAINE read (for the President) notes of a similar case, with numerous exostoses on the long bones of the extremities. They occurred in a boy aged eighteen years, and had been growing for five years. About eight of them had been removed by operation. Well developed bursæ were found over each.

Dr. F. J. SMITH showed two cases. 1. A case of Progressive Muscular Atrophy in a man aged thirty-three. The disease had begun when he was eighteen, and he had been under observation almost continuously ever since. The symptoms were exceedingly well marked and perfectly typical, with the exception that pain in the abdomen had been a more or less prominent feature since the beginning. The record of the last fifteen years consisted simply in alternate conditions of improvement and relapse, the patient being admitted to hospital unable to feed himself from weakness of the arms; under good feeding and rest in bed he would recover sufficiently to be discharged until another relapse set in. A sister had died from the same disease. 2. A case of Idiopathic Tetanus in a man aged twenty-four. The symptoms had been gradual in onset, a fortnight elapsing before well-marked opisthotonos was present. The interest of the case chiefly lay in the powerlessness of chloral hydrate to affect the disease, when hypodermic injections of morphia immediately produced amelioration in the symptoms and a cure in the course of twelve or fourteen days. The patient was now quite well except for pains in the arms on waking in the morning.

Mr. JOHN POLAND showed a case of Comminuted Fracture of the Patella successfully treated by Wiring. The patient, a drayman aged twenty-nine, fell a distance of thirty feet, his left knee coming in contact with the stone pavement. His fall, however, was broken before he reached the ground. Considerable swelling about the joint obscured the precise condition of the fractured patella. At the time of the operation it seemed at first impossible to bring the fragments of the bone together, on account of the extensive comminution, the wide separation of the fragments, and the difficulty experienced in immediately recognising the proper position of the various pieces. The way in which this had been accomplished by means of sutures of pure silver wire (of small size) was indicated on a diagram. The patella then moved as a whole. The joint was syringed out with a strong solution of carbolic acid. The torn extensor tendon and capsule were finally united over and at the sides of the patella. The wound was dressed (antiseptically) on the second day, and subsequently at intervals of four and three days for four weeks, when it was almost healed. The temperature rose to 101° on the second day; after that it remained normal, with the exception of the sixth day, when it reached 100°. The patient was discharged from the hospital at the end of eight weeks with a plaster-of-Paris splint. Six weeks afterwards a small sinus formed, through which one of the wires was readily removed. The rest remained in position. The patient could now (at the end of twelve months) walk well, without the aid of a stick or support of any kind, and flex his knee to some extent.

Dr. A. T. DAVIES showed a case of Xeroderma. R. D——, aged fifty-five, general dealer. Subject to winter cough for four years. Has noticed since birth an almost universal dryness of the skin of his body. This condition is seen to be most marked on the extensor surfaces, approaching in character to ichthyosis, especially on the arms and back of the thighs; elsewhere, except the face and genitals, this condition of skin is more that of xeroderma.

Mr. COTMAN showed a case of Pityriasis Pilaris. The patient was a boy aged nine years, who had measles four months ago; following this, a roughness of the skin came on, which developed into pityriasis pilaris of a rather exaggerated form.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, NOV. 7TH.

DR. GWYNNE, PRESIDENT, IN THE CHAIR.

Eye Injuries.—Mr. S. SNELL introduced two patients. In one there was a rupture of the globe of the eye with absence of the lens and entire absence of the iris. Vision was then $\frac{2}{60}$, and the patient read Jaeger with + glass. The tension and form of the eyeball were good. The accident took place last January and was caused by direct violence. At the time the eyeball was filled with blood, and in consequence of pain and other causes enucleation was considered on more than one occasion. The patient was a man aged forty-two. The second case was one of rupture of the choroid and optic nerve from direct violence. The accident happened eight weeks previously. There was no light perception.

Fibro-myoma of Uterus.—Mr. R. FAVELL showed two specimens. In one case an attempt to remove the tumour was made, as by mechanical pressure it was causing urgent symptoms. Abdominal section was performed, but the adhesions being so strong between the back of the tumour, and the pelvis and rectum being so intimately adherent, the attempt at removal was abandoned. The patient died fourteen days afterwards from peritonitis. At the post-mortem examination, the Fallopian tubes were found much thickened and enlarged, and the ovaries undergoing cystic degeneration and strongly adherent to the sides of the pelvis. In the other case the patient had died from sudden and profuse hæmorrhage. The tumour weighed about 7 lb.; the sinuses in the capsule of the tumour were very large near the cervix, and it appeared as if the hæmorrhage had taken place by the opening of one of them.

Temporo-maxillary Articulation.—Mr. FRANK HARRISON read a short paper on this subject. He contrasted the action of the joint in carnivora, ruminants, and in the human subject, showing that the various movements produced a modification in the shape of the teeth. In the human subject he showed the production and use of the cusps in action and repose. He also described the triangular construction of the jaw, being equilateral, having its base between the condyles (four inches) and its apex at the lower central incisors.

Laparotomy.—Mr. PYE-SMITH read the notes of a case of unsuccessful laparotomy. The patient, a boy aged thirteen, was seized with colicky pains in the abdomen after watching a football match on a cold day. He was seen by Dr. Sinclair White on the third day, and a milk diet was ordered, with small doses of morphine. Pain, with vomiting and constipation, continued for four days, when the vomiting ceased and the abdomen became distended. A saline aperient produced several liquid motions. For five days more the case seemed going on favourably, but on the twelfth day a tender lump was discovered two inches above the right internal abdominal ring. Next day tenesmus set in, and another lump was found to be pressing on the anterior wall of the rectum, just above the anus. On the fifteenth day of the illness Mr. Pye-Smith saw him in consultation with Dr. White. There was then general and moderate distension of the abdomen. The chief tenderness was over the iliac and hypogastric regions, and here an elongated tumour was somewhat indistinctly felt, lying transversely, and feeling to be continuous with the mass felt per rectum, which distended the recto-vesical pouch. No fluctuation could be made out. The rectum was empty. No peristalsis was visible. No rigors had occurred, but the temperature had ranged from 99° or 100° to 102° F., and the pulse from 90 to 132. Respiration 24, markedly thoracic; tongue furred; pain not markedly paroxysmal; no passage of blood or mucus. Intussusception seeming by no means improbable, inflation was tried before recommending an exploratory laparotomy. Neither air nor water injections effecting any change in the tumour, the abdomen was opened with antiseptic precautions. Several coils of small intestine were matted together by firm recent adhesions. At the spot where the lump had been first observed there was a small collection of pus between the parietes and the adherent bowel. This was drained, and the wound closed. After the operation the patient's father recollected that a fortnight before the commencement of his illness the lad had fallen, whilst running, with a hard green apple in his pocket, which had struck him just above the right groin, and been completely crushed. This, it was suggested, might have been the cause of the peritonitis. Thirty-six hours after the operation a quantity of offensive pus was discharged per anum, and the lump there was found to have disappeared. On the evening of the next day, however, the pulse began to fail, and the patient died on the following morning, three days after the operation. No necropsy was permitted. Mr. Pye-Smith expressed the opinion that, had the diagnosis and pathology been clearly recognised, the treatment should have been limited to rest, with light diet and opium, supplemented by the evacuation of local abscesses as detected.

Mr. PYE-SMITH also showed a specimen of Kyestine Urine.

THURSDAY, NOV. 21ST.

Muscular Atrophy.—Dr. BURGESS showed two cases. One, a female aged twenty-nine, had a severe attack of acvte atrophic paralysis at puberty. The deltoid, supra- and infra-spinatus, biceps, and brachialis anticus muscles were wasted and paralysed on both sides. On the right side there was palsy of the upper pectoralis major, hypertrophy of the upper trapezius, and great looseness of the shoulder-joint. Recent wasting of certain muscles of the left hand was doubtful. There was loss of power and bulk in the extensors of the right knee and hip. The second case was one of infantile paralysis, in which the triceps and upper pectoralis major were affected, in addition to the group of muscles constituting the "upper arm type of Erb."

Colotomy.—Dr. GWYNNE read the notes of a case where lumbar colotomy was performed for obstruction due to malignant disease of the upper part of the rectum. The patient, a woman aged forty-six, had suffered for some months from constipation, alternating with diarrhœa The operation was performed at her own house, on Dec. 3rd, 1886, in the left lumbar region. She was very much relieved, and her health so far improved that she was able to return to the duties of her shop. Two years after operation she passed blood from the bladder, and for some time this became a constant occurrence. She then began to lose flesh, and, after six months of extreme suffering, died on May 19th, 1889. On opening the abdomen post mortem, the bowels were pale and distended with gas, but apparently healthy. At the upper part of the rectum a large, apparently cancerous, mass was found, adherent to the spine behind and to the bladder in front, and completely surrounding the gut. A large fistulous communication was found between the rectum and bladder. Various nodules were discovered in the course of the bowel towards the anus, and a large ulcer about three inches from the anus, obviously malignant in character. Several large secondary tumours were found in the liver. Microscopic examination of the primary and secondary tumours showed their nature to be cylindrical epithelioma.

Ancient Surgery.—Mr. ARTHUR JACKSON read a paper on this subject. He alluded to Mr. Watson Cheyne's work on "Antiseptic Surgery" as showing how much the ancients did in the way of Listerism; but he did not agree with Mr. Cheyne's conclusion that the great surgeons of the sixteenth century obtained the success they did with their antiseptics "more as the result of chance than from any glimpse of the true principles which were at work." Mr. Cheyne had referred to Paré having ascribed atmospheric influence upon wounds not so much to the air itself as to miasms contained in it, which Mr. Jackson thought was getting pretty near the present theory of putrefaction. Mr. Teale, in his address on Surgery at the Leeds meeting of the British Medical Association, had alluded particularly to certain advances which had been made in surgical methods in recent times, such as the treatment of a wounded artery by double ligature and division of the vessel between, the substitution of Lister's sounds for older methods in the treatment of stricture, the emancipation from red-tape rules of drainage, peritoneal stitching, &c. Celsus, who lived about the commencement of the Christian era, recommended ligature of a wounded artery in two places and its division between. Galen, in the second century, advised digital compression, and, if that failed, to seize it with a hook and twist it moderately; in some cases to cut the artery across and let it retract; in others to ligature it or to apply the actual cautery. How all this practical knowledge came to be lost it was difficult to say; it was astonishing to read Paré's protest against the

Digitized by Google

actual cautery for the arrest of hæmorrhage, and to think that as lately as 1830 it was used for that purpose after amputation at the Sheffield General Infirmary, and that even at Guy's Hospital it was not discarded till after the middle of the last century. Mr. Jackson instanced the suturing of divided tendons, and less frequently divided nerves, as practised by Galen and his contemporaries. In reference to drainage, he quoted the writings of Thomas Gale, surgeon to Henry VIII., describing the hollow "tentes" used, which were of soft linen, cotton wool, silver, and copper, bigger at one end than the other for fear they should slip into deep wounds. They were first dipped in precipitate of mercury mixed with oil of roses. Stitching the edges of the peritoneum together, the drainage of the peritoneal cavity, and the application of heat in the shape of hot wine to the bowels, were mentioned by Galen, Celsus, and Paré. Tapping for hydrocephalus, the radical cure of an enterocele by tying the sac and cutting off all below the ligature, the tapping of the chest for empyema and the use of injections, the use of catheters resembling Lister's sounds, artificial ears, noses, eyes, limbs, and a "platter" for the roof of the mouth after the effects of the "Spanish sicknesse," were among a numerous list, quoted by Mr. Jackson, of surgical methods known in the seventeenth century, and many of them as early as the tenth. He also quoted a long list of instruments which were as common then as now, of much the same character and founded on the same ideas as in the present day. In conclusion, he said that he did not wish to run down the surgery of the present day or to minimise the labours of those whom we knew and admired, but he thought that if we had an opportunity of realising the work done centuries ago we and our generation would benefit greatly.—Dr. Gwynne, Dr. Martin, Mr. James, Dr. Law, Dr. Porter, Mr. Knight, and Dr. Burgess took part in the discussion.

CLINICAL SOCIETY OF MANCHESTER.

TUESDAY, OCT. 15TH.

DR. LESLIE JONES, PRESIDENT, IN THE CHAIR.

Recent Advances in Dermatology.—Dr. BROOK gave an address on this subject. He said the main reasons which caused the study of skin diseases to be neglected by the great majority of medical men were the confusing polymorphy of the eruptions and their frequent change of nomenclature. The former were due to the intense complexity of the skin as an organ and to its great variation in structure in different sites. The latter was not capriciousness, but the natural result of the evolution of our knowledge. This was instanced by the history of the terms "lichen" and "pityriasis" from Willan's time to the present day. A scientific scheme of classification was as yet impossible, and had become more so than ever since the recent influx of bacteriological investigations. The active diseases fell mostly under the head of blood diseases, nerve diseases, and parasitic diseases. The former arose from the action of poisons (auto-inoculations, as in gout, rheumatism, &c., or from drugs or foods). They had so close a connexion with many purely nervous affections (e.g., urticaria) that it was necessary to suppose that the poisonous matter exercised a specific action on various nerve centres in the skin resembling the specific action of poisons in the various nerve centres. Amongst the nerve diseases a great advance had been made by the formation of the group of Hydroa, the dermatitis herpetiformis of Duhring, and the userythema (or scar erythemata) of Unna, comprising lupus erythematosus and the chronic atrophic form of non-parasitic sycosis. The group of parasitic diseases was continually growing in number, and would probably be found finally to institute the great bulk of all the dermatoses. Their development was often greatly influenced by the general health and external surroundings of the patient, and this had led, as formerly, in the case of tuberculosis, to the presumption that many of them were constitutional. One of the newest additions to the class was the group caused by a low form of animal organism—the psorosperm (Darier),—which had been found in a peculiar disease, *psorospumose folliculaire végétante*, characterised by a plugging of the pito-sebaceous orifices and the development of large tumours, chiefly about the groins. Similar bodies are found in Paget's disease of the nipple, where they appear to be the direct cause of the epitheliomatous growth (Wickham). In the degenerative affection known as pityriasis rubra, several distinct varieties have been singled out, of different origin, course, and prognosis. Apart from the introduction of various new drugs and modes of application, the recent tendency of dermatological therapeutics had been largely in the direction of antiparasitics.

Dr. JUDSON S. BURY showed a woman, aged twenty-four, who presented a combination of Scleroderma and Raynaud's Disease; and also exhibited water-colour drawings from (1) a case of Xanthoma Diabeticorum, and (2) a case of extensive "Port-wine Mark."

Dr. THOMAS HARRIS showed a case of Herpes Zoster, and other cases were shown by Dr. COLLINS.

Reviews and Notices of Books.

History and Pathology of Vaccination. By EDGAR M. CROOKSHANK, M.B. Two Vols. London: H. K. Lewis. 1889.

[PRELIMINARY NOTICE.]

THIS is the latest and, in many respects, a most important addition to the vast literature of vaccination. The work has, we understand, been already sent to the members of the Royal Commission. Whilst deferring for the present any critical notice of its argument, it may be of interest to note its scope and character, more especially as the conclusions arrived at are at variance with those commonly held concerning the nature and remedial value of vaccination. And in the first place, the author must be congratulated, not only upon his industry and research (which has led, amongst other things, to the discovery of some hitherto unpublished Jennerian manuscripts), but also upon the exceedingly handsome manner in which his volumes have been published, including the reproduction of numerous plates after Jenner, Ceely, Peuch, and others. The first volume is devoted to a historical and critical review of the subjects; the second consists of reprints of the most famous papers—viz., those of Jenner, Pearson, Woodville, Birch, Ceely, Badcock, and several more, memoirs dealing with all sides of the question, and with which the profession of to-day is mostly unacquainted. The first volume will, however, doubtless attract the most attention, and it certainly merits careful perusal. The subject has been dealt with temperately, and, so far as we can judge at present, without prejudice, whilst the text is free from the attacks upon Jenner's character which disfigured the book published by Dr. Creighton, with whose views Professor Crookshank in the main agrees. The work opens with chapters devoted to the practice of small-pox inoculation, from the earliest times and in all countries, and the methods of its performance. Of especial interest is the account given of the practice in Great Britain, and the description of the Saltarian method of mild inoculations. Then it is shown how this measure failed to exterminate small-pox, and how Haygarth propounded his system of registration and isolation as the only effective measure, anticipating thus the ideas of many in the present day. Then Professor Crookshank deals with cow-pox, and shows how the "tradition of the dairymaid" as to its being protective against small-pox was endorsed by others before the time of Jenner, and how Mr. Jesty (whose portrait forms the frontispiece to the work), the Dorsetshire farmer, proved his faith in its efficacy by inoculating (in 1774) his wife and sons with vaccine. The "Life and Letters of Edward Jenner" forms the title of a most interesting chapter, in which the steps of his investigations, his doubts, difficulties, and the opposition he had to contend with, are illustrated largely from his letters. One of these is reproduced in *facsimile*. In subsequent chapters the text of his first paper, rejected by the Royal Society, is minutely scrutinised and compared with the revised edition, published in the following year. It is shown how Jenner held that cow-pox, small-pox, and many other diseases had

Digitized by Google

their origin in horse-grease; and how, as his experience grew, he attributed failures to protect from small-pox to vaccination from spurious cow-pox. His inoculations with horse-pox were made between the first (rejected) and second (published) "Inquiry," and incorporated in the latter. Professor Crookshank then shows, in a series of chapters, how "vaccine lymph" has been derived from various sources—e.g., from human small-pox, as by variolation of the cow (Ceely and Badcock), from cattle plague (considered by Moorhouse to closely resemble human small-pox), from sheep-pox, goat-pox, cow-pox (in which Ceely's classical descriptions are quoted and several of his drawings reproduced), and from horse-pox. This latter subject, after descriptions of the views and practice of Jenner and Loy, is enriched by the accounts of outbreaks at Toulouse and Alfort, especially one observed at Toulouse in 1880 by M. Peuch. There is a comparatively brief chapter upon the introduction of vaccination into foreign countries, in which it is maintained that the erroneous idea that cow-pox was small-pox of the cow was the main factor in the acceptance of the new method. Then follows a chapter on the progress of vaccination in England. Here, again, the phrase "variolæ vaccinæ" was misleading. Used by Jenner, it implied more than he intended, for he did not think that cow-pox was derived from small-pox, but rather that both had a common origin in horse-pox. The propagation of erroneous ideas as to the nature and efficacy of vaccination is attributed to Baron, the biographer of Jenner, and the theory of cow small-pox was established through the reports of Ceely and Badcock. Yet, as Professor Crookshank points out, neither cow-pox nor horse-pox is associated with outbreaks of small-pox; and he not only declares, with Chauveau, that cow-pox is absolutely distinct from small-pox, but holds, with Dr. Creighton, that both the bovine and equine affections have more analogies with syphilis than with variola. He concludes, therefore, that vaccination is futile, seeing there is nothing in common between variola and vaccinia, and that there is consequently no parallelism between vaccination and the Pasteurian methods of protective inoculation by attenuated virus. Nor has small-pox been exterminated. "The Jennerian method has for nearly a century struggled for existence with the support of the cow small-pox theory and the numerous and ingenious explanations of failures embodied in the assertions of spurious cow-pox, inefficiently performed vaccination, inferior quality of lymph, deficiency in the number and quality of marks, and the misinterpretation of statistics" (p. 484)—a statement of such sweeping character that it will surely be incumbent on the writer to add still further to the literature of the subject in support of it. Rejecting vaccination as futile, he sees no reason why inoculation should not be practised on the attendants on small-pox cases; but looks to compulsory notification and isolation, and not vaccination, as the real means for coping with the spread of small-pox. Such being the main lines of Professor Crookshank's contribution to this vexed question, he will not be surprised at learning that he has failed to carry conviction to our minds respecting the real point at issue—viz., the *efficacy of vaccination*.

A Text-book of Human Anatomy: Systematic and Topographical, including the Embryology, Histology, and Morphology of Man, with special reference to the requirements of Practical Surgery and Medicine. By ALEXANDER MACALISTER, M.A., M.D., F.R.S., F.S.A., Professor of Anatomy in the University of Cambridge, and Fellow of St. John's College. With 816 illustrations. London: Griffin and Company. 1889.

PROFESSOR MACALISTER'S text-book of human anatomy is by far the most important work on this subject that has appeared in recent years, and has the great advantages of not only fully dealing with descriptive and topographical anatomy, but of also being a complete treatise on human embryology, histology, and morphology. It therefore follows the lines of the best of its predecessors in treating its subject thoroughly and comprehensively, and in many respects it is not only equal, but even superior to them. The histology of the tissues is most ably and lucidly described in the first hundred pages of the volume, and in this part we also have clearly shown the embryonic characters and subsequent changes in development in the various systems which lead up to their adult conditions in man. The anatomy of the bones and joints is then taken seriatim, and the many modifications in the ordinary nomenclature, which are rendered imperative when man is studied from a morphological standpoint, are very striking, and will be at once perceived on reading Professor Macalister's account of the human skeleton. We may draw the especial attention of the teacher and student to the descriptions of the vertebral column and the skull as examples of such changes. The descriptions of the soft parts are not arranged under the various systems as usual, but topographically in the order in which they are dissected by the student—viz., back, upper extremity, thorax, abdomen, lower extremity, and lastly the head and neck. But although this is an excellent systematic arrangement, is it the most common for dissectors, and is not the lower extremity usually dissected by the student immediately after the upper extremity and before the trunk? The muscles, vessels, nerves, and viscera are described as they would consecutively come into view in methodical dissections, and directions as to the methods for displaying them are given as in an ordinary dissector's manual or guide. The author truly says it is the only order in which the student really learns them, or should learn them, for it is in the dissecting-room alone that a knowledge of anatomy can be acquired; but we question, although this one book may now be used instead of two, if, except among a very few students, it will displace such works as those of Ellis, Cunningham, and Cleland from their well-deserved position as guides for dissection. It will rather compete with Quain's Anatomy and other standard text-books in systematic anatomy, and be mainly studied by those students who have had a preliminary biological training, for without this it will be impossible for the student to understand and appreciate the chief excellences of the book. It must be clear to anyone who refers to any description, such as that of the branches of the external carotid artery, how great is the advantage of this early scientific education in the study of human anatomy, and how essential it has become, if one is to learn properly this groundwork on which all our knowledge of medical science and art ultimately depends when this science is dealt with from its just point of view by a thoroughly scientific teacher. There are many references to the bearing of anatomical facts on medicine, surgery, and physiology; but these are comparatively scanty, and are in the main insignificant in value and importance when placed by the side of the concise and accurate descriptions of the various structures and their bearing on morphology. It is unnecessary to specify the few details in which we should differ from an author who has written a work which is destined to be placed side by side with Professor M. Foster's Physiology and the late Professor F. M. Balfour's Comparative Embryology as examples of modern science-teaching at Cambridge. The illustrations vary in precision and clearness; a large number of them are new and of the highest excellence, and will be heartily welcomed by anatomists, but some of those which have seen former service have become deteriorated in the definition of their outlines, and are not so clear as might have been wished. Names of structures, some in Latin, others in English,

Digitized by Google

in the same plate, exhibit an incongruity which should have been avoided. The work would have been more appreciated by the learner if some of the illustrations—such as those of the bones of the skull, hand, and foot—had been of larger size, even though the cost of the book would have been increased thereby. But every anatomical teacher, and every student who desires to study human anatomy in a scientific as well as a practical manner, will thank Professor Macalister for devoting so much time and trouble to the writing of this book. We shall look with interest for his catalogue of varieties and their statistics—for, as he says, the normal anatomy of man is only obtained by a study of averages,—and for the history of the progress of anatomical discovery, both of which he has promised us will appear in the future, and will prove of great value to the anatomist. The typography is very clear and distinct, and the publishers are entitled to credit for the way in which the work is got up.

Egypt as a Winter Resort. By F. M. SANDWITH, F.R.G.S. Pp. 153. London: Kegan Paul and Co. 1889.

This is an excellent work for those who purpose to winter in the dry climate of Egypt and avoid the cold, wet, and fog of our own country. The author states his object to be "not to try and prove that Egypt is the best health resort in the world, but to give reasonable information about its climate to those who have practically decided against the respective merits of sea and mountain, and are in search of pure dry desert air where rain is almost unknown, and where fog, strong winds, and cold are never felt." This he has succeeded in doing in a very readable form, and has given a great amount of information which must prove useful not only to invalids but to those in health, especially with regard to Cairo and its suburbs, and Luxor. The mean temperature, as shown by the records of five years, 1884–88, at the Khediveal Observatory, in the suburb of Cairo, was 70·2° F., and the rainfall only 1·22 inches; in 1887 rain fell only on fifteen days, and snow is unknown. The only drawback appears to be the *khamseen* wind, which, blowing from the south or south-east, is attended with clouded sky, grey atmosphere, and a very fine sand suspended in the air. It occurs about Easter; "it usually continues three days, but may in rare cases last as many as seven days," but may again appear. The number of days on which it prevails in any one year may range between four and twenty. It does not appear to affect invalids more than the rest of the Europeans. The death-rate at Cairo among European residents during the last seven years was only 21·8 per 1000; that of the native population is rather more than double, owing principally to the mortality of infants, of whom one-third die within the first twelve months. The climate of Luxor seems to be even more dry than that of Cairo. There are two good hotels there, affording accommodation for about 150 visitors. Both at Cairo and Luxor invalids must be very careful to be in the house before sunset, for the night air is very cold in comparison with that of the day. The climate seems well suited for cases of chronic phthisis, but in the advanced stages and in acute tuberculosis the patients would be better "at or near home." For though, in Egypt, "he gains sunlight and sunheat during the day, and runs a chance of his disease being arrested; against this he must balance draughts and irksome travelling, a paucity of fireplaces, food and habits to which he is unsuited, and exile from his home comforts and best friends." Cases of chronic bronchitis and asthma as a rule do well, and the climate seems particularly suited to cases of rheumatoid arthritis. The account given by the author of the sanitary condition of Alexandria and Ramleh, and especially of the conservancy arrangements, is not such as to induce anyone voluntarily to take up their abode in either of them. We have no hesitation in recommending this book to those who desire good information on the principal points involved in the selection of a bright, dry, and healthy winter resort.

New Inventions.

A PATENT SAFETY REIN.

WE have had an opportunity of seeing Sergeant's patent safety rein in use, and so far as we are entitled to form an opinion from a single inspection, think it a very decided improvement upon the existing system. The driving rein passes through the harness pad tirrets and the rings of the bit; it is then brought back through a ring attached to the saddle strap and secured by a spring hook to a ring on the crupper. It is stated to be an effectual means of stopping a runaway, to prevent rearing and falling back, after a few lessons to cure jibbing and kicking, to obviate the necessity for a Martingale or bearing-rein, and to greatly diminish the risk attending pulling up suddenly on asphalte and slippery roads. So far as we could judge it appears to fulfil many of these indications; as regards the others, such as curing jibbing and kicking, it would be absurd to offer an opinion without more opportunities of watching and testing its effects. It certainly seems to give a great command over a horse without requiring the use of a severe bit—one of the most cruel things ever invented,—and to obviate the risk of rearing. There has long been a controversy on the subject of bearing-reins, which undoubtedly, as too often used on carriage horses in London, are cruel instruments of torture. We believe, as a result of careful examination, that, except possibly in a very few instances, Sergeant's rein would give all the advantages of a bearing-rein without its drawbacks, and would put it out of the power of the coachman to inflict a great amount of suffering for the sake of what he considers a fashionable and high-bred appearance of his horses. If we had either a puller or a kicker, we should at once adopt the safety rein, and give it a fair trial. We are not disposed to agree with the inventor that the appliance is graceful, but there is nothing objectionable in its appearance. The rein can be seen and obtained at Brown's Harness Factory, Great Quebec-street, W.

AUSTIN'S SANITARY CYLINDER AND POROUS DISINFECTOR.

THIS is a porous cell with a copper wire handle. It is closed at the top, and contains alkaline permanganate. Suspended in a cistern, or water waste preventer, the permanganate slowly diffuses out in quantity sufficient to colour the water, and so promote the work of disinfection. The contrivance is simple and efficient, and although permanganate cannot be regarded as a very powerful disinfectant, it has real value, and is a good deodoriser. The Austin Sanitary Cylinder Co., Limited, Queen Victoria-street, E.C., are the patentees.

KING'S AUTOMATIC DISINFECTOR.

THIS disinfector consists of a brass box with two chambers, a cover which closes with a bayonet-joint, and a small conical aperture at the bottom. By means of a strip of metal it can be suspended in a cistern so that a regulated flow of the material in the box is ensured. The disinfectant used is permanganate of potash, which is placed in crystals in the upper part of the box. The apparatus and the material are alike cheap, and it is said that the amount of the latter consumed is so small that the expense

Digitized by Google

of disinfecting a closet does not amount to more than a penny a week. The patentee is Geo. H. King, Ashmore-road, Paddington.

Analytical Records.

CADBURY'S COCOA.
(CADBURY BROS.)

MESSRS. CADBURY maintain the fame they have so long enjoyed. The cocoa examined by us was very soluble in water, contained no starch or other foreign ingredient, and only 20·5 per cent. of fat. In other words, it was of excellent quality, easily digestible, and not too rich.

SAINT MARCO LITHIA WATER.
(HEARON, SQUIRE, AND FRANCIS, 5, COLEMAN-STREET, LONDON.)

This natural water is recommended as useful in gout, rheumatism, stone, &c. It is drawn from springs on the Marucheto Estate, Tuscany, and is, we are informed, held in high estimation in Italy. The published analysis by Professor V. Amoroso shows in English figures 154 grains per gallon of mineral compounds, including 2·52 grains of carbonate of lithium. The rest consists mainly of the sulphates, chlorides, and carbonates of calcium, magnesium, sodium, potassium, iron, and manganese. We found 172 grains per gallon in the sample we examined, and verified the presence of lithium. Certainly the water is interesting, and deserves a careful trial in this country. It is slightly saline in taste, and is not too strong to be used at the table.

CARNABYN.
(HOOPER & CO., 55, GROSVENOR-STREET, LONDON.)

We can best describe this preparation by saying that it suggests port wine and the extracts of meat and malt, but we cannot profess to describe its exact composition. It is certainly a very powerful nutrient stimulant, and will in suitable cases be very valuable. It is perfectly clear and tastes somewhat like a very fruity and somewhat sweet port. Its alcoholic strength is high—namely, 16·46 per cent., by weight equal to 35·47 of proof spirit. It yielded 14·2 parts in 100 volumes of solid residue, and 0·5 of ash containing phosphates. Every physician will see the proper [illegible] avoid the improper uses to which such a wine may be put.

THE STRETTON HILLS MINERAL WATER COMPANY, SALOP.

We have received from this company samples of various aerated beverages made from the water of the Crom Dale Spring. This water is evidently very pure, for the so-called soda-water only contained eight grains per gallon of solid matter and no trace of organic matter. Of the seltzer, potash, and table waters there is not much to remark except that the seltzer contained 10·02 and the potash 2·7 grains of salt in the 10 oz. bottle. The ginger ale did not strike us as quite satisfactory, for the evaporated residue extracted with ether left an acrid, burning taste on the tongue. No lead or other heavy metal was found in any case.

A COMPLIMENTARY DINNER.—On Tuesday evening, at the Leeds Club, Albion-place, Mr. C. G. Wheelhouse, F.R.C.S., was, on the occasion of his leaving that city, entertained at dinner by the Board of the General Infirmary, the medical officers of the various local institutions, and other medical friends. Mr. R. Benson Jowitt, Chairman of the Infirmary Board, presided. The chairman, in proposing the toast of "The Guest of the Evening," referred to Mr. Wheelhouse's long connexion with the Infirmary, and to the valuable assistance he had rendered it, not only as a surgeon, but in its management. Mr. Wheelhouse, in returning thanks, expressed his appreciation of the compliment paid to him.

THE PATHOLOGY OF CHOREA.
To the Editors of THE LANCET.

SIRS,—Might I crave a little space in order to point out an error into which Dr. Garrod has fallen in his criticism of my letter on the above subject? In that letter I say: "Rheumatism is essentially a disease of the motor apparatus. Chorea is essentially a disease of the motor centres. In this broad pathological statement we have the clue to the explanation of the fact that chorea is common in rheumatic subjects." Referring to this, Dr. Garrod says that if this were so "we might surely expect a similar association of chorea with gout and rheumatoid arthritis in spite of the rarity of these maladies in early life." In this criticism Dr. Garrod ignores (no doubt unwittingly) a very important part of my letter, for in the latter part of the paragraph to which he refers it is stated in the most explicit manner that chorea is most common in females and in young people, and that "the rheumatic constitution is by no means necessary to the production of chorea. *Youth and sex are more important predisposing agencies.*" Chorea is essentially a disease of youth, the vast majority of cases occurring between the ages of seven and fourteen. Causes which excite it then do not excite it in adult life. Gout and rheumatoid arthritis are not possible causes, because they do not occur during the age of liability to chorea; rheumatism is a possible cause, because it does occur during that age.

In discussing the question of the relationship of rheumatism and chorea it must ever be borne in mind that the cases of chorea in which this relationship exists are, after all, only a minority. In the majority there is no such relationship, and the choreic symptoms have in them to be explained without reference to any of the changes associated with the rheumatic process. To advance one hypothesis for the explanation of the rheumatic cases, and another for the non-rheumatic, is to advance two hypotheses in explanation of one set of phenomena. In science that is scarcely admissible.

I am, Sirs, your obedient servant,
Cadogan-place, Dec. 7th, 1889. T. J. MACLAGAN.

OPERATIVE TREATMENT OF FLAT-FOOT.
To the Editors of THE LANCET.

SIRS,—In your issue of Dec. 7th, Mr. T. S. Ellis of Gloucester comments adversely upon osteoplastic operations for the cure of flat-foot, holding osteotomies for this condition "to be unwarranted, because unnecessary." I am well acquainted with Mr. Ellis's views—and I think them admirable—on the restoration of deformed regions by the energetic renewal of abeyant motor functions; and in the treatment of such conditions as lateral curvature of the spine I conceive no better principle of treatment can be enunciated. But when this principle is applied to the treatment of such deformities as extreme knock-knee and flat-foot, as Mr. Ellis urges it should be in his published writings, I can but fear that it will suffer in reputation by its extension to a group of conditions wholly different from those where its advantages have been indubitably proved. The group to which the principle is properly applicable includes all cases of deformity not dependent upon actual alteration in the shapes of bones. On the other hand, in that group of cases where bony surfaces are profoundly altered in their shape or direction, the principle in question must certainly give place to that of plastic renovation; for though I would not deny to the former method the possibility of effecting a cure after long and laborious use, yet such a result, as compared with the early and satisfactory outcome of a radical operation, cannot escape condemnation as an undue procrastination of recovery. In hospital practice this element of time cannot be left out of account; it is of the greatest importance to the disabled patient and to those dependent upon him that he should be restored to usefulness by the most rapid means compatible with safety. And on this last issue, with the statistics of aseptic osteotomy before me, I can but express surprise that Mr. Ellis should now feel any doubt as to the "justifiable" nature of such operations.

I am, Sirs, yours obediently,
Manchester, Dec. 10th, 1889. ARTHUR W. HARE.

THE LANCET.

LONDON: SATURDAY, DECEMBER 14, 1889.

IT is evident from the discussions which took place at the recent meetings of the General Medical Council that considerable importance is attached by that body to the position which has been assigned by the Local Government Act to examinations for diplomas in Public Health and Sanitary Science. For the future the best and the most remunerative posts of medical officer of health are only to be held by those who either possess such diplomas or who have had other special opportunities which prove their competency for such office; and it is very natural that, since the State and the public will henceforth look to the various licensing bodies to grant these diplomas to none but those who are experts in that branch of medicine, anxiety should be expressed by the General Medical Council as to the fitness of the various examinations as a true test of competency.

Since none but fully qualified medical practitioners are now allowed to enter as candidates for the examinations, there is much to be said for the view of those who maintain that, provided the candidates exhibit the knowledge required of them, it is a matter of indifference how, when, and where that knowledge has been acquired. The General Medical Council, however, have thought otherwise, and in June last they resolved that, as a preliminary to entrance to any examination for a public health diploma, candidates should produce evidence to the effect that, since the date of their qualification in medicine, surgery, and midwifery, they had devoted a definite period of time both to chemical work in a laboratory and also to practical public health work under the holder of some public health office. These conditions have evidently not been readily assented to by some of the examining bodies; one intends to take legal opinion as to the competency of the Council to impose such restrictions, and others have through their representatives pressed strongly for some relaxation of the conditions.

The grounds of objection to them are several. In the first instance, it is held that they are, in some respects, quite unnecessary; and one body—namely, the University of London—has shown this as regards chemistry by eliminating practical chemistry from their list of subjects of examination for their new degree of Doctor in State Medicine. With this attitude we have much sympathy, in so far as the London University is concerned, because every candidate whom they admit has already passed an examination in practical chemistry, the stringency of which certainly exceeds that usually demanded by bodies granting diplomas in Public Health. But the London University probably stands alone as regards the character of its Preliminary Scientific Examination, and there are many bodies who could not properly take their stand beside that university in respect of any objection to a period of preparation in a chemical laboratory. Other bodies demand that the two periods of special preparation should, if the candidates desire it, be undertaken during the ordinary medical curriculum, and this especially if that curriculum is to be made to extend over five instead of four years. On the other hand, it is held that the time of a student is amply filled without taking up any special subjects, and the extension of the period for the ordinary curriculum has been proposed mainly on the ground that that period was admittedly too short. On this point we think that the two conditions which the General Medical Council have decided to impose might well stand on a different footing. Ordinary chemical work might properly be so taught during the ordinary curriculum as to render repetition of instruction in the subject, after qualification, unnecessary. Indeed, this is already done by certain bodies, of which the University of London is the type. And not only so, but it is generally understood that it is not the duty of a medical officer of health to undertake advanced chemical work. Inquiries as to this which have from time to time been made of the Local Government Board, who have statutory powers to define the duties of medical officers of health, have elicited the opinion that quantitative analyses and analyses of articles of food do not properly come within the province of a health officer, and this the more because, under a special statute, the work of such chemical analysis has been distinctly delegated to another set of officers—namely, the county and borough analysts. For reasons such as this, we could wish that no hard-and-fast line should be decided on in this matter; and, whilst we are convinced that the ordinary chemical training of the medical student needs supplementing for the duties of a health officer, we trust that the motion which was adopted by the General Medical Council, to the effect "that the Executive Committee shall have power to admit exceptions in special cases to the rules regulating the diplomas in sanitary science,..... " will be so interpreted as to cover the point as to the date of acquiring the needed chemical competency.

As regards the period of practical instruction with a health officer the matter is, in our opinion, different. Such work is not, in any sense, included in any ordinary medical curriculum, and hence the requirement ought not to be allowed to interfere with that curriculum. The work should certainly be undertaken subsequently to the obtaining of a registrable medical qualification. But here another difficulty has been raised. Medical officers of health are naturally those who are most competent to give the needed instruction. The best of them have, however, in most instances, undertaken to give their whole time to the duties of their office, and they would be unable to take pupils for such a purpose as is indicated without the assent of the body or, as it at times is, the multiple bodies who have appointed them. Others, again, may have neither time nor inclination for the task; indeed, one of the leading health officers in the United Kingdom, who holds office in a university town where a special diploma is granted, has already refused to undertake any such new duty. Such an attitude will necessarily tend to drive candidates to seek the needed tuition at the hands of less competent officers. For this and kindred reasons we feel we must concur with those who hold that this matter has been decided on somewhat prematurely.

But whilst we say this, our sympathy is entirely with the General Medical Council in their desire to secure that all

Digitized by Google

who hold these diplomas shall be possessed of special and expert knowledge of the subject they have to deal with. Hitherto appointments to health offices have been offered at a remuneration so miserable and inadequate that those most competent for the duties have been deterred from even applying for the posts. And, since the possession of health diplomas will in the future give the holders a statutory right to those offices where the opportunities for public health work will be on the largest and most important scale, candidates seeking them must be prepared to submit to such conditions as to stringency of examination and evidence of previous training as are necessary to satisfy the public that they are really competent to act as official advisers in that branch of medicine in which they claim to be possessed of special knowledge.

M. PASTEUR, in the pages of the *New Review*, has contributed an account of his labours, which should carry conviction to the mind of any impartial reader; and at a recent meeting of the Society of Arts the subject of Hydrophobia was thoroughly treated by Dr. ARMAND RUFFER, in a lecture that was followed by an interesting discussion. It may be worth while to recall the salient points of these proceedings, so as once more to emphasise the fact, which cannot be too often impressed, that the control of this terrible malady lies entirely in the power of the State. Dr. RUFFER at the outset of his address, pointed out that rabies never occurs spontaneously, so that it is quite possible by restrictive measures to stamp it out. He showed that the disease is almost ubiquitous—that neither climate nor season has any special influence upon its prevalence; and he described how it may be propagated to man, chiefly by the dog, but also by other animals, notably by the wolf. He sketched briefly the symptoms of hydrophobia, showing how that term is a misnomer, since it is inability to swallow from spasm of the throat, and not dread of water as such, that is an essential feature of the affection. Dr. RUFFER showed how futile all attempts at the cure of hydrophobia by drugs, sweating, &c., had been, and proceeded to discuss the measures for its prevention. These were two in number—(1) the registration of all dogs and the wearing of a collar by each such dog, all others being at once destroyed; and (2) the destruction of all stray dogs, and the muzzling of all others, together with quarantine for all imported dogs. The first was shown to be inefficient, and in Belgium had been proved to be so. The second measure alone was of use, and its value has been amply proved by results. The rest of the lecture was devoted to the consideration of the efficacy of M. PASTEUR'S method, and facts and statistics were quoted from several places where inoculations have been practised. At the Paris Institute it was shown that, each year, as the methods of inoculation have improved, the mortality amongst the inoculated has diminished, so that it is probable that this year it may not amount to 0·5 per cent.; and the lecturer contrasted such a result with the mortality of 80 per cent. amongst the non-inoculated bitten on the face (of which kind 280 have been treated by PASTEUR), and 15 per cent., the lowest mortality amongst those bitten, in any part of body. As to the allegations that persons have died from PASTEUR'S treatment who have never been bitten by rabid animals at all, Dr. RUFFER said that there was absolutely no foundation for them. The evidence in favour of inoculation over cauterisation or any other plan of dealing with the disease is in fact overwhelming. The discussion elicited many interesting points. Mr. ADAMI related his personal experience of the inoculation at the Pasteur Institute, whither he had resorted after receiving a post-mortem wound in examining the body of a rabid deer. Professor RAY LANKESTER urged the point that in an island like ours it must be possible by general muzzling and quarantine to exterminate rabies as thoroughly as wolves were exterminated in the reign of EDWARD III. Mr. W. HAUGHTON, however, thought that muzzling could not be efficiently performed, and that rabid dogs would escape it, attributing the undoubted diminution of the disease in 1885-86 to the wholesale destruction of stray dogs. Dr. G. FLEMING alluded to the injury and loss inflicted by rabies upon domestic animals, and stated how he had come to abandon the view he formerly held that it arose spontaneously. Rabies had been stamped out of the Island of Bourbon for more than half a century, though it raged with great virulence in Mauritius. By quarantine New South Wales had prevented its introduction into that colony. Dr. FLEMING forcibly advocated muzzling, which must be universal and applied for a certain time. Dr. DRYSDALE endorsed these views, and said that Professor VIRCHOW had remarked that he thoroughly agreed with PASTEUR'S splendid discovery, but it was not required in Germany, where they muzzled the dogs. Professor VICTOR HORSLEY said there could be no practical difficulty in enforcing quarantine, and that nothing short of universal muzzling could extinguish the disease. Sir JOSEPH LISTER, who occupied the chair, dwelt upon the precautions taken in the Pasteurian method to prevent the introduction of putrid matter into the inoculation material, and quoted M. PASTEUR'S statement as to the ease with which England could, in a comparatively short time, get rid of rabies, by means of universal muzzling and a rigid quarantine.

The almost complete unanimity of opinion expressed at this meeting can hardly be matter of surprise; for the arguments upon which such opinion is based are incontrovertible. On the one side we have an infective disease chiefly affecting dogs, and capable of being transmitted to man and other animals,—a disease of the most virulent nature, which no known remedy, short of protective inoculation, has yet been able to cope with. On the other side, we have a country, separated from other lands by a sea barrier, and able, therefore, to prevent, with due diligence, the importation from without of diseased animals. So that once rabies is stamped out within the island, its recurrence could be absolutely and for ever prevented. But we are a slow, and yet, according to many, a practical people; and the majority, not realising the nature of this dread malady, and urged perhaps by a sentimental view of the muzzle in relation to the dog, think that scientists are making "too much ado" about such a matter, which does not touch our commercial interests (although Dr. FLEMING showed how considerable are the losses to trade &c. from rabies), and some, moreover, seem to think that restrictive legislation of any kind ought not to be tolerated. Such people would extend the doctrine of the liberty of the subject even to the rabid dog. We may hope for more

Digitized by Google

reasonable counsels to prevail, and that, in spite of practical difficulties which are by no means insuperable, the Legislature will lose no time in following an example so long set by Germany, and with such satisfactory results. However, until we have succeeded in stamping out the disease, the treatment of hydrophobia must be that introduced by M. PASTEUR, which, as Dr. RUFFER amply showed, has been successful beyond expectation. It has stood the test of much opposition and criticism, and has established a firmer footing than any other line of treatment ever suggested for this most intractable of diseases. That there may be other means of eliminating the virus is, of course, possible; but as yet no such methods have been declared. It is surely a remarkable thing, and one not very creditable either to the intellect or the heart of our nation, that we seem to be unable to enforce either the only known method for preventing the disease in this country, or to establish means for its treatment. Universal muzzling and quarantine are regarded by many influential people with an aversion equal to that they feel to the foundation of a Pasteur institute. Meanwhile the dire malady claims its victims, whom we have to send to a foreign land for treatment. How long will it be, we wonder, before the folly and the shame of such ineptitude and impotence are brought home to the mind of the British nation!

THE Royal Statistical Society does well at intervals to elect for its President a distinguished member of the medical profession. Statistics have been nowhere more impressive or useful than in regard to health and mortality. In this region they have been invested with an interest for human beings in all conditions of life and climate that have gone far to rob them of that quality of dryness which deters so many from attempting to master them. It would be difficult to name two men who have done more to clothe the dry bones of statistics with flesh and blood than WILLIAM FARR, M.D., and WILLIAM A. GUY, M.B., Presidents, respectively, of the Society in 1871–73 and 1873–75. These are the medical names that figure honourably in the list of Presidents from 1834 onwards along with those of eminent statesmen and publicists. The name of the present occupant of the chair may be less known popularly than those, but only because his work has been more directed to the use of statistics in military questions affecting the health of our troops in the various parts of our vast empire. In this connexion, however, few names are better known or more honoured for sound and substantial work than that of Surgeon-General GRAHAM BALFOUR, F.R.S., who reviewed the various events of interest to statisticians in the past year, particularly the second meeting of the International Statistical Institute in Paris, where the English society was strongly represented. He acknowledged with much grace the kindness and hospitality of the French Government, and showed how many topics of interest to all countries had been discussed—questions of labour and wages, of the productive results under different agricultural tenures, of commercial crises, &c. He gave an exceedingly interesting account of the system adopted by the police in Paris for the quick and certain identification of prisoners previously convicted, based chiefly on photography and certain anthropometric measurements, including the height, the length of the body when seated, the length of the arms extended, the length of the head, the breadth of the head above the ears, the length of the forearm (*coudée*), the length of the middle finger and little finger, the length of the foot, the length and breadth of the external ear, &c. The unfortunate prisoner who tries lying as to his previous history quails when confronted with such details. They are not produced till after his trial and condemnation. As illustrating the value of private enterprise in statistical questions as distinguished from State-aided undertakings, Dr. BALFOUR selected for praise the volume of Mr. CHARLES BOOTH, one of the Vice-Presidents, entitled "Life and Labour in East London," and claimed for it that it had "narrowly localised" the poverty of London, discovered its extent, gauged and differentiated its intensities, and cleared the ground for the labours of other and less exact sciences.

We have not space to dwell on Dr. BALFOUR'S illustrations of the precautions to be observed in all statistical work, and especially of the error of endeavouring to obtain results from operating with ratios instead of the actual numbers. We must not, however, omit to notice his very spirited and effective vindication of the work of army medical officers in reply to an unfortunate remark of Sir EDWIN (then Mr.) CHADWICK at a meeting of the Sanitary Institute in 1883, that "there has been a continual neglect of sanitary experience in the army down to the present time." He reminds their critic that army medical officers have no power to carry out any of their own recommendations, *however urgent their need may be*, and it is too well known that the hard heart of the Treasury can only be moved by popular clamour and alarm, which too often only follow national disaster, such as the break-down in our commissariat and other arrangements in the Crimean War. Dr. BALFOUR shows that long prior to this period members of the Army Medical Department had been doing valuable work, beginning with that of Sir J. MCGRIGOR at the end of the Peninsular War, which consisted mainly in creating a system by which the health of troops, and particularly special outbreaks of disease among the troops, in various parts, were duly reported to him. This led the way in 1835 to an inquiry into the expense incurred in replacing soldiers who died or were invalided. The present Lord GREY, then Lord HOWICK, appointed Dr. HENRY MARSHALL, Deputy-Inspector of Hospitals, and Lieutenant TULLOCH to this work. In the following year, Dr. MARSHALL having to retire on the ground of ill health, Dr. BALFOUR was nominated by Sir JAMES MCGRIGOR to take his place, and in rapid succession they produced reports and recommendations of a more extensive and general character than those of the previous twenty years on the health of our troops in all parts of the Empire. Dr. BALFOUR passes hastily and modestly over these reports. But some of them at least were very valuable and have become historical. Dr. PARKES—himself a host to refute the charge of Sir EDWIN CHADWICK—says that the history of sanitary science affords no instance of the removal of disease to a more wonderful extent than in the case of the West Indies, where, fifty years ago, the usual time for the demolition of a regiment of 1000 strong was five years, and

Digitized by Google

occasionally in a single year a regiment would lose 300 men. Now this dreaded service has lost its horrors, and he attributes the credit very largely to the reports in 1838 of TULLOCH and BALFOUR, which Dr. BALFOUR disposes of in this unostentatiously brief way:—"In 1838 we presented a report on the West Indies." Not only did they frame these various reports, but they prepared a form of sanitary report to be forwarded annually by the medical officer in each foreign station. Their work was interrupted by the Crimean War; but it never died, and has been productive of similar work in the navy and in the departments of other countries. We feel gratified that the Statistical Society should have paid its highest honour to one of our profession, as quick in his detection of bad work as he has been indefatigable in the promotion of sound knowledge in the department of vital and sanitary statistics, and we congratulate him on his spirited vindication of his department.

THE President of the Institute of Actuaries has been inaugurating a new session of his Society by an address, in which he treats of many things, and among them of the functions of the medical examiner. For some reason Mr. SUTTON has taken umbrage, and complains that the medical officer, "not content with his own duties, has been putting on the uniform of the actuary and rushing in where actuaries fear to tread." What may be the justification or reason of this complaint we do not know, and our complainant does not enlighten us. We must therefore be content to say that the case which he puts is certainly a very rare one and one respecting which we should be glad to have particulars. The medical man who is ambitious of distinction in the melancholy science of annuities must be something of an intellectual curiosity. But that by the way. Mr. SUTTON appears to favour a proposal to substitute a probationary period for medical examination. This is no new thing. It is largely adopted in industrial insurance business where the amount of the transactions is too small to bear the expense of medical fees. And in the beginnings of life assurance business it was not customary to obtain a medical report at all. There are many men still living who can remember the old days when an applicant was required to appear personally before the board of directors and answer questions put then and there as to his past and present health and mode of living. The medical certificate was an improvement upon this crude method of examination. But the old medical certificate worked badly and unsatisfactorily to all concerned, and it was left for the late Mr. THOMAS WAKLEY, the founder of THE LANCET, to suggest the scheme which in the end solved all the difficulties of the case. The great inconvenience of the old method arose from the fact that the proposer paid the medical fee and received the certificate for transmission to the office. Hence the medical examiner was compelled to submit his report to the proposer himself, and ran considerable risk of giving rise to disappointment or even ill will on the part of his patients, while at the same time he was prevented from entering upon any detailed or minute report. These difficulties were met by the simple expedient of sending the medical examiner's instructions and his fee from the office of the company. He thus became an officer of the society and his report a private document, which the proposer had no right to see. This scheme was embodied in the prospectus of a company, which was established early in the fifties, and of this prospectus, indeed, it became the distinctive feature. But its merit was generally recognised, and in a few years the practice so inaugurated was universally adopted. So it has continued to the present time; and if Mr. SUTTON shows some disposition to speak slightingly of the medical officer and of his office, we shall be quite content to appeal from him to the invariable practice of the companies and the constantly repeated testimony of the directors and managers of prosperous societies, who know and do not hesitate to say that the very favourable mortality, which well administered and progressive life offices are almost always able to show, is chiefly due to the care and skill exercised in regard to the medical selection of risks.

That the actuaries can give an equally good account of their stewardship we are not quite sure. For many years past there have been accumulating in their hands enormous masses of statistical materials calculated, one would suppose, to throw light on many important questions of prognosis. But we are not aware that this statistical matter has been worked up, and its results deduced on any commensurate or even on any considerable scale. No doubt it is easy to find fault, and we have no desire to demonstrate our prowess in that direction; but, since the discussion has been set on foot, it may be useful, and serve more than a temporary purpose, to remind our critics that they in turn owe something to society over and above the safe custody and eventual destruction of the medical reports which during the past forty years have been produced at a great expenditure of time and pains, and committed to their care.

Annotations.

"Ne quid nimis."

THE REGISTRAR-GENERAL'S FIFTY-FIRST ANNUAL REPORT.

THE Registrar-General has just issued his Fifty-first Annual Report dealing with the vital statistics of England and Wales in 1888. It is satisfactory to note that the date of its appearance is earlier by nearly a month than that of any previous report of this series, although three months later than the publication of the report of the Registrar-General for Ireland for last year. With regard to Scotland, the entire population of which is smaller than that of London, the last issued Detailed Annual Report relates to the year 1886. The English report just published shows that 1888, from a statistical point of view, was a year remarkable for low rates of marriages, births, and deaths. The marriage-rate was 14·2 per 1000, the lowest rate on record being 14·1 in 1886; the birth-rate was 30·6, the lowest rate recorded in this country since the first year of civil registration (1838), when the registration system was but imperfectly carried out, and the number of unregistered births was undoubtedly considerable; and the death-rate was 17·8, which was "by far the lowest rate as yet recorded." The marked reduction in the recorded rates of marriages, births, and deaths in recent years has been partly attributed by some to an over-estimate of the present population of England and Wales. It is

Digitized by Google

obvious, and to be regretted, that more than eight years after the last census estimates of population must partake very much of the nature of mere guesses. The Registrar-General, however, after careful study of all available figures, again expresses his deliberate opinion that the estimates upon which the rates in recent years have been calculated, if at all overstating the actual population, are not sufficiently inaccurate to invalidate the calculated rates for comparison with those in previous years. We may, therefore, fairly assure ourselves that the marked reduction in the recorded death-rate in recent years represents a real reduction in the rate of mortality, implying improved health and increased longevity. We may further assume that, judged by the remarkably low death-rate, the health-condition of the country in 1888 was more favourable than in any previous year on record. The Registrar-General calls attention to the fact that the next lowest rate to that in 1888 was recorded in the preceding year, 1887. It is also pointed out that "in each of the eight years of the current decennium the death-rate has been under 20·0, whereas in no single previous year had it ever fallen so low." The mean annual rate in the last eight years was 19·05, while the mean rate in the last completed decennium, 1871–80, was 21·38; in other words, the mortality in the past eight years has been more than 11 per cent. lower than that in the preceding ten years. This remarkable decline in the national death-rate, which has been maintained, and at an increasing rate, since 1875, points conclusively to some powerful and persistent influence; and its coincidence with the full operation of the Public Health Acts of 1872 and 1875 seems fully to justify its attribution to the awakening of public interest in sanitary reform, of which awakening those Acts were the outcome. With regard to the unprecedentedly low rate of 1888, it was undoubtedly due in great measure to the exceptionally favourable meteorological conditions of the year. The coolness of the summer months and the mildness of the winter months favourably affected the mortality at all ages, but more especially the mortality of infants. The report points out that the rate of infant mortality, measured by the proportion of deaths under one year to registered births, was 136 per 1000, and lower than in any previous year on record, excepting 1879 and 1881, "each of which years was also distinguished by exceptionally low diarrhœa mortality." That the low rate in 1888 was, however, in great measure also due to causes more satisfactory to the sanitarian than mere fortuitous meteorological conditions, it is only necessary to refer to the mortality from the zymotic or specific febrile diseases; the deaths "ascribed to this class of specially preventable diseases" were in the proportion of 2097 per million persons living. This rate, the Registrar-General reports, "was far lower than that recorded in any previous year in the current decennium, and no less than 44 per cent. below the mean rate in the preceding decennium 1871–80." With the single exception of diphtheria, the death-rate from each disease in this group in 1888 was below the decennial average, and "in the majority of cases, if not actually at the minimum point yet attained, not far above it." The decline, compared with this average, was perhaps most marked in the death-rates from scarlet fever, enteric fever, and typhus, which last disease appears to be steadily dying out. On this occasion we have confined ourselves to a brief notice of the main features of the report as bearing upon the more important vital statistics of the year. We are glad, however, to note a valuable contribution to the statistics of epidemiology under the heading "Zymotic mortality in relation to sex and age." The broad basis of facts upon which these statistics are constructed give them undeniable value, and the subject is one of undoubted interest, both from a medical and public health point of view. We shall, as occasion offers, again refer to these instructive and suggestive figures, and in the meantime we may especially recommend them to the notice of medical officers of health, both on account of their inherent interest and of the statistical method adopted in the construction of the tables on which the conclusions are based.

EUTHANASIA FOR MURDERERS.

THE success of the lethal chamber for producing euthanasia in the inferior animals seems to be keeping alive a constant desire to introduce the same merciful process for murderers. Dr. Samuel Abbott, Secretary of the Massachusetts State Board of Health, is the latest advocate of this change in the mode of carrying out the extreme penalty of the law. If a change must be made, he argues, if the gallows must be superseded by some more humane method of taking a life forfeited to the State, let us take the most certain, the most humane, the most inexpensive, and the most easily managed of all the methods which science has supplied; let electricity with its risks and troublesome arrangements, involving necessity for skilled electricians as executioners, be set aside; and, let a simple apparatus, in which the criminal can sleep to death, be the new advancement in the art of taking life, *cito, tuto, et jucunde*. Dr. Abbott proposes a lethal chamber, and suggests that carbonic oxide should be the lethal agent. The culprit is to be placed in a small closed chamber, and, when all is ready, a free current of the lethal gas is to be introduced into the enclosed space, so that its occupant may be instantly rendered unconscious, and, by continuance of the process, narcotised to death. Two minutes is the time which is allowed from the beginning to the end of the proceeding. Without pledging ourselves to the statement that in every case human life could be extinguished painlessly in the space of two minutes, we fully admit that death by the lethal method could easily be carried out if the change were desirable. We may go a step further, and say that it would be possible to carry out euthanasia by a still better method than the one above referred to. There are, however, questions involved which have to be considered most carefully before any wise statesman would commit himself to the change proposed. First and foremost amongst these is the question whether it is advisable to give to murderers, and to them alone, the privilege of being deprived of life by absolute euthanasia. What have they, of all men, done that the pains of death shall not fall upon them? And why should they, of all men, go out of existence in a gentle sleep, knowing no more of their death than of their birth? The common theory is that by taking the lives of criminals, the law deters others, by the awful dread of the penalty, from committing the crime for the punishment of which the penalty is cast. Is euthanasia likely to be a deterrent? No man who has been in the practice of medicine for five years would admit anything of the kind. Practitioners of medicine learn very soon the history of those, by no means a limited class, who would willingly die at any hour were it not for the fear of the suffering that might attend the supreme event. If men never committed suicide, or if we could trust a man under sentence of death to his own devices in his cell, with appliances for suicide at his command, there would be some reason in the argument. But when we know that life is so little valued by a large class wearied of it, and that many would gladly seek death if the latter would only come without a pang, it is surely the perfection of folly to offer that class the very method of death which it does not fear. Such a proceeding is like offering a premium on murder. Why, then, alter the present state

Digitized by Google

of things? In the present method of execution by hanging there is not one bit too much of the deterrent element; for, as it is well known physiologically, there is no infliction of special agony beyond that common to dying from any sudden and violent mode of death.

MEDICAL PRECAUTIONS AGAINST CARRYING INFECTION.

MISS COBBE must feel rather dissatisfied with the scanty success of her attack upon the medical profession. She may possibly have been visited with some slight compunction as to her right to accuse the profession and to call upon it to answer her accusations. But we are not sanguine upon this point, as ladies of the vigilant order think they have divine rights over all sorts and conditions of men, even over those whose boast and property it is to prevent as well as cure disease. The profession has other work to do than to rush into newspapers and make humble explanations of its methods of disinfection. It would, at least, have been but generous in Miss Cobbe had she, in her second letter to *The Times*, admitted that she had underrated the services of the profession in the matter of disinfection and prevention of disease. It will be strange, indeed, if she can still allow herself to think that precautions taken against other visitors are going to be all relaxed in favour of medical students, or that medical men take no more precautions against infection than were thought necessary in that hazy region of "years ago," to which she has to go for her case against them. We decline altogether to go into particulars with Miss Cobbe, and would as soon think of debating with her the remedies for scarlet fever as the methods by which its spread is to be prevented. These matters are not only the subject of inquiry just now by a committee of high authority appointed before Miss Cobbe took up this branch of special Providence, but are the constant care of every medical practitioner worthy of his profession.

THE BOWMAN LECTURE.

THIS lecture was delivered before the Ophthalmological Society on Nov. 15th by Professor Edmund Hansen Grut of Copenhagen, who took for his subject the Etiology of Squint. He commenced by assuming that the anatomical position of rest of the eyeballs in emmetropia is that of slight divergence, whilst the functional position, or that which the eyeballs assume in consequence of the desire for distinct distant vision, is one of parallelism. He then endeavoured to show that convergent squint originates in, and is maintained as the result of, an innervation which induces a contraction in the internal recti beyond what is necessary, so that when this is suspended the squint disappears. On the contrary, divergent squint is the expression of an innervation occasioning convergence, permitting the eye to assume its anatomical position of rest. In the absence of any paresis or abnormal attachment of the muscle divergent strabismus can only arise when the anatomical position of rest is a divergent one. Divergent squint, therefore, differs in its etiology from convergent squint. The normal movement and position of the eyes are materially affected by habit and exercise, and their influence in the production of squinting is certainly considerable. No better proof of this can be given than the complete concomitance of lateral movements and of the movements of convergence of an occluded eye, when the ordinary stimuli as the disposition to fusion of images are wanting. An explanation is afforded of persistent convergent strabismus by assuming a considerable displacement inwards of the functional position of rest in consequence of persistence in acts of convergence preventing complete relaxation of the internal stimuli. In periodic squint the anatomical position of rest is one of unusual divergence; the squint which accompanies efforts of accommodation moves the functional position of rest inward, so that it nearly coincides with a parallel position of the optic axis, and hence, except during strong accommodation, no squint is evident. A habit of convergence is developed whenever frequent or continuous convergence is necessary, and this is most common in hypermetropia. In divergent strabismus there is no shortening or contraction of the external recti, because there is no innervation leading to their excessive action. The condition arises from complete relaxation of the internal recti, as a consequence of which the functional gives way to the anatomical position of rest; but if this latter position is one of parallelism, no absolute divergence will occur. Absolute divergence is not caused by cessation of convergence any more than the normal condition of inability to diverge leads to convergent squint, and this is shown by the different effect of tenotomy in the two conditions of external and internal squint; for if the former were, like the latter, due to muscular contraction, tenotomy of the external rectus should be as effective as tenotomy of the internal rectus, which is not the case. The lecturer passed a warm eulogium on the merits of Sir William Bowman as a scientific worker, and ended his discourse with a review of the different theories that had been advanced in regard to the nature and etiology of strabismus.

BURIAL REFORM.

UNDER the ominous heading of "Overcrowded Cemeteries" the Duke of Westminster writes, urging the necessity of fresh legislation to correct the many abuses which exist in our present mode of burial. His Grace repeats what has been frequently noticed in these columns, that the large number of bodies interred in the metropolitan cemeteries—100,000 in twelve acres at the Brompton, a quarter of a million in the seventeen acres of the Tower Hamlets—would be no cause for alarm were they properly buried. An infinitely greater number could, he remarks, be buried with harm to none if the mode of burial were in accordance with sanitary law. How thoroughly true this is may be proved by the following simple calculation. In suitable soil 1000 graves can be made in an acre without any overcrowding. If each body is buried in a perishable coffin and in the earth, the resolution of the body is effected in a few years, and another burial can take place without in any way diminishing the capacity of the grave for more interments. In other words, graves and graveplots can be made capable of holding an almost unlimited number of bodies, while vaults, catacombs, and bricked graves can only hold a very limited number. If the metropolitan cemeteries had from the first been managed as burial-grounds in the strict sense of the word, they would now be in the same position as many of our older churchyards, holding the dust of ages past and still having room for more. Burial reform is not a thing of yesterday. More than two centuries ago Sir Christopher Wren strongly denounced the practice of burying bodies in the vaults of churches and advocated suburban burial grounds. And in the middle of last century the mortal remains of Bishop Wilson were, in accordance with his expressed wish, buried in the churchyard of Kirk Michael and not under the church, he wishing to set a good example, and not to sanction so dangerous a practice. And yet in THE LANCET of last week there was a notice of an application for power to bury a body in a vault beneath the parish church of Bebington, which has a large congregation at its Sunday services. And though the memory of good Bishop Wilson still remains in the island of which he was for more than fifty years bishop, his excellent example was

Digitized by Google

not followed, several of the Manx churches having large numbers of dead in the vaults beneath them. Much has been done by individuals, collectively and individually, to set a good example in these days, and by no one more than the Duke of Westminster. It is well known that the burial of his late lamented son, Earl Grosvenor, was a model of simplicity in all its details, and he still holds the position of president of the Church of England Burial Reform Association, whose indefatigable secretary, the Rev. F. Lawrence, has done so much to make burial reform popular with all classes. But much remains to be done. Burial under churches ought to be absolutely forbidden, the soil of a public cemetery should be for the use of all the parishioners, and not partitioned off by walls into vaults or bricked graves. No coffins except those of a perishable kind should be allowed. These reforms will, it is to be feared, need legislation for their general adoption.

A NATIONAL LEPROSY FUND.

WE are glad to learn that important steps are being taken to carry on the work sketched out by the Father Damien Memorial Committee. A National Leprosy Fund is to be established, in aid of which a dinner will take place at the Hôtel Métropole on Jan. 13th, H.R.H. the Prince of Wales having kindly consented to preside. Amongst those who have intimated their intention to be present are the Duke of Norfolk, the Duke of Fife, the Archbishop of Canterbury, Cardinal Manning, the Lord Mayor, Lord Rothschild, Sir Andrew Clark (President of the Royal College of Physicians), Mr. Jonathan Hutchinson (President of the Royal College of Surgeons), Sir James Paget, Sir Henry Acland, Sir Prescott Hewett, Sir Joseph Fayrer, Sir Lyon Playfair, Sir Charles Russell, Sir Frederick Leighton, Sir George Paget, Sir Henry Thompson, Sir Edward Sieveking, and Sir E. Saunders. It may be hoped that under such auspicious circumstances the proposed fund will be well started, and that support will flow to it from all quarters. The subject is one of Imperial concern—in which the interests of England, and especially of India and the colonies, are largely bound up. It is proposed that the interest arising from such fund should be devoted to the medical treatment and care of indigent lepers in the British Empire, and that a sum of money be set apart and placed under the control of trustees for the endowment of two studentships, one student to make the United Kingdom and the remainder of Europe his field of investigation, and the other to go abroad and study the disease in India, China, the colonies, and elsewhere. Sir Somers Vine, Adam-street, Adelphi-terrace, is the hon. secretary to the Dinner Committee.

FEEDING TIME AT THE WORKHOUSE.

IN spite of some variation in the practice of different lands and ages as to methods observed in eating, we may take it that civilised custom throughout Europe has been wise in sanctioning the knife and fork as indispensable aids at the principal daily meal. Such, however, is not the universal opinion, and an opposite view has even been accepted by such qualified judges as the Chester Board of Guardians. These gentlemen, at a recent meeting, discussed the question whether, in the case of paupers' dinners, fingers and teeth were not sufficient, without the addition of instrumental help such as we have mentioned. After some conversation it was decided that on Christmas Day, and on that day only, knives and forks hired for the occasion should be issued to the workhouse inmates. The magnanimity of this concession will doubtless be duly appreciated by the ratepayers when the mere decency of taking dinner in the ordinary way is compared with the rule of Chester Workhouse—that the paupers' meat shall not be cut, but torn and devoured. A further advantage will accrue to some who are happy enough to enjoy a workhouse dinner on Christmas Day. Toothless inmates who have hitherto bolted unmasticated meat (with what results are best known to themselves and the union medical officers) will have an opportunity of mincing beforehand the indigestible morsels. We may imagine their comfort, and perhaps even picture the contentment of thoughtful guardians, that thus a small saving of expenditure on illness has been avoided. For all their guardian kindness and rare sense of ordinary decency let the poor and the country thank them, if even it be granted for one day only. Is there no other union yet more wisely liberal which will recognise in the pauper, though destitute, something more than a carnivorous animal, and will risk the extravagance of providing him daily with a plain knife and fork that he may eat like other men?

NEUTRALISATION OF THE BACILLUS TETANI.

IN June last Professor Sormani of Milan announced to the Lombard Institute of Sciences the results of his experiments on the neutralisation of the tetanigenous microbe—results which seemed to justify his conclusion that iodoform, iodol, and corrosive sublimate are absolutely destructive of the bacillus in question. To these disinfecting agents he has, as the result of further experiments, added three more—namely, chloroform, chloral hydrate, and camphorated chloral, the latter being, he alleges, in a marked degree efficacious; while camphor and camphorated alcohol he found inert. On a general review of the whole, however, he gives the preference to iodoform. Seven rabbits were inoculated with materials charged with the tetanigenous virus. From six of these, after an interval of twelve hours, the foreign body was removed during the period of incubation; from the seventh the substance was removed only when the first symptoms of local tetanic convulsions had declared themselves. In all these animals the wound was scraped and thereafter freely medicated with iodoform. The seventh rabbit died of tetanus. Of the first six, five were saved. From this Dr. Sormani concludes that medication of wounds with iodoform ought to be practised before the setting in of the first tetanic symptoms. Nevertheless, even during declared tetanus, the application of iodoform to the wound is capable of disinfecting it and of removing from it all trace of virulence. Wounds and sores treated with iodoform, especially wounds or sores contaminated with earth, yield results highly welcome to the surgeon—such medication preventing the access of that fatal tetanic symptom which, having once declared itself, leaves but little chance for skilled interference. Dr. Sormani gave confirmatory proof of his thesis by cases of tetanus in hospital, where iodoform opportunely applied saved the patients, and where, from its use having been unfortunately suspended, two lives were sacrificed.

AN INDUSTRIAL SCANDAL.

ADVOCATES of a system of labour free from State regulation may study with advantage the details of a recent instance of industrial over-pressure. At Dewsbury, a few days ago, a firm of woollen manufacturers were convicted in thirty-seven cases of employing for an excessive number of consecutive hours boys under eighteen years of age. Some of these youths had been at work for almost a whole day of twenty-four hours without intermission, except at meal times. A more scandalous example of neglect of the most obvious physical requirements could hardly be adduced. It is needless that we should enlarge upon its mischievous possibilities. At an age when the development of mind and body is proceeding actively, and absorbs in itself a large amount of vital energy, when growing organs—notably

Digitized by Google

the lungs—almost invite the action of disease, a strain which would be severe at any age is thrown upon the body with almost certainly injurious effect. The work is done, perhaps, at no great pecuniary outlay; but the cost in health, if such a system were persisted in, could not but be, as regards the manhood of the country, most ruinous. On consideration of all the circumstances, a total fine of £52, with costs, must appear to many besides ourselves a very lenient sentence.

TESTS FOR MELANURIA.

R. VON JAKSCH (*Zeitsch. für Phys. Chem.*) has been endeavouring to obtain more satisfactory tests for the condition known as melanuria. As ordinarily described, this is characterised by the passage of urine which becomes black or very dark on the surface as soon as it is exposed to air. On standing, a black pigment is deposited, which is termed melanine, and is distinguished from other colouring matters in urine by its insolubility in water, alcohol, ether, and acids, with the exception of strong nitric acid, which decomposes it. R. von Jaksch finds that when perchloride of iron is added to thick and highly coloured urine a precipitate is formed. On the addition of a very dilute solution of perchloride of iron only a light blackish-brown cloud results. A tolerably concentrated solution gives a greyish-white precipitate. After filtration, fresh addition of perchloride of iron gives rise to a dark colour and a light precipitate. With an excess of perchloride of iron the grey precipitate is dissolved and the black precipitate remains, and is only dissolved with a very large quantity of the reagent. The colouring matter thus precipitated is a mixture of different substances. It is soluble in hot formic acid and in lactic acid. It is insoluble in acetic acid, chloroform, glycerine, &c. It contains nitrogen, iron, and sulphur. With ferrocyanide of sodium and carbonate of potassium the urine gives a rose-red colour if the solution is dilute, and a dark-red colour with concentrated solutions. Mineral and organic acids change this to a deep blue, and after a time a precipitate forms. This precipitate, separated by filtration, dissolved in carbonate of soda and treated with hydrochloric acid and perchloride of iron, gives a precipitate of prussian blue. This last reaction is not peculiar to melanine, and is only a confirmatory test after the presence of melanine has been proved by perchloride of iron. Melanuria, that is to say, the presence of melanine in urine, is an important element in the diagnosis of melanotic cancer.

DEATH UNDER CHLOROFORM.

WE have to record yet another fatality under chloroform. M. F——, a woman aged forty-one, was admitted into the Samaritan Hospital for Women, Marylebone-road, on Nov. 27th. On Monday, Dec. 2nd, it was decided to operate upon her, and, in accordance with the routine custom of the institution, chloroform was administered from a Junker's inhaler. When half-way through the operation, the patient showed signs of dangerous depression, the pupils became widely dilated, and the respiration and heart's action ceased. The medical evidence given at the inquest was to the effect that the patient died from syncope produced by the chloroform inhalation. The same authority stated that this was the only death which had occurred at the Samaritan Hospital, as a result of an anæsthetic, out of a total of 4000 administrations. According to Richardson, the mortality under chloroform is 1 per 2500 or 3000, while Coles of Virginia gives it at 52 deaths in 152,260 administrations, or about the same percentage. Authorities vary widely in their estimates, some placing the mortality far higher and others stating that these figures are too high. While a certain number of patients probably lose their lives through lack of care or experience upon the part of the chloroformist, others—as in the case of Mr. Clover, working with his dosimetric method, and the case under comment, when every care and the utmost skill failed to ward off a fatal result—appear to succumb to the depressing action of the drug. It is an incontestible fact, to which regard is sometimes not given, that in proportion to the length of time the patient is subjected to the action of chloroform is the danger of failure of the vital processes increased. Deaths under chloroform have occurred when almost every form of inhaler has been employed, so that, although many possess especial merit—and notably Clover's, which but for its cumbersomeness would have become more popular,—none can be said to do more than assist the efforts of the administrator to maintain the vapour within safe limits.

THE SUBCUTANEOUS ADMINISTRATION OF IRON.

PROFESSOR ROSENTHAL of Vienna, writing in a Pesth medical journal on the subcutaneous administration of iron, states that this method is advantageous in the cases of delicate neurasthenic persons who suffer, as such often do, from atonic dyspepsia. Here even small doses of iron taken by the mouth will sometimes produce disorder of the stomach. In severer forms of disease, such as pernicious anæmia, malarial cachexia, and the graver forms of leukæmia, there does not appear to be any advantage in the employment of the hypodermic method of administering iron. Two new preparations are recommended by Professor Rosenthal for hypodermic use—viz., the peptonate and the oleate of iron. He states that he has never seen any bad results follow subcutaneous injections of iron preparations, and he explains the fatal consequences that have occasionally been reported as following injections into vascular tumours of the head, by the fact that the vessels composing such tumours are generally closely connected with the veins of the dura mater. He has frequently seen venous enlargements in the legs undergo shrinking after being injected with dilute perchloride of iron, no dangerous symptoms ever ensuing.

THE NEW "POLIAMBULANCE" IN NAPLES.

FROM the report of the Poliambulance or Dispensary which was established in Naples some two years ago by a number of philanthropic medical men for the benefit of the very poor, it would appear that an excellent work, both from a charitable and from a scientific point of view, is being carried on. There are some thirty medical men connected with the institution, who divide amongst themselves the charge of the various departments, and who undertake to do duty at night in cases of emergency, and to visit patients requiring it at their homes, all gratuitously. During the twenty-six months with which the report deals, 9500 cases have been treated, about 1000 of whom were visited at their own homes, and 250 passed on into hospitals. The number of night attendances was 354. The surgeons performed several amputations, and other major operations at the patients' homes, and the physicians had a considerable number of infectious cases to visit. The members of the staff in charge of the various departments mention a few interesting matters. Thus, Dr. Alfredo Rubino, the well-known editor of *La Riforma Médica*, who is vice-director of the poliambulance, and who takes charge of the department for nervous diseases and electro-therapeutics, reports that locomotor ataxy and infantile spinal paralysis have been the most numerous of the diseases of the cord, and remarks that he has not been able to trace the first to a syphilitic origin nearly so often as some other

Digitized by Google

authors, only 16 per cent. of his cases being referable to this cause; while Fournier ascribed a syphilitic origin to no less than 90 per cent. of his cases. The electrical treatment of infantile paralysis proved very successful. There were two cases of "hæmato-myelie" of traumatic origin, which were treated very successfully by rest and vaso-constrictor remedies during the early stage, and by the constant current and iodides later on. Dr. Masucci, who has charge of the department for diseases of the ear and throat, mentions that he was able to cure all the gummata he met with in and about the pharynx, which were mostly ulcerated, by the insufflation of subiodide of bismuth.

THE INFLUENZA EPIDEMIC.

THE influenza epidemic, as we anticipated, is rapidly spreading over the Continent, and as rapidly abating at St. Petersburg, thus following the course of many previous outbreaks of this remarkable and highly infective malady, notably that of 1847. In Vienna it has become very prevalent, and has also appeared in several towns in Poland, in some of which a large proportion of the population are affected. The *Daily News* Vienna correspondent writing on the 10th, states that the first ascertained case in that city was that of an assistant physician in the General Hospital. The illness began on the last day of November and lasted for five days. Prof. Nothnagel has given a clinical lecture on the subject, and urged the study of its etiology. Indeed, there is now a great opportunity offered to bacteriologists. In Berlin the disease has also broken out, and amongst the sufferers is reported to be Professor Bergmann (who, however, we regret to learn from another account, is said to be suffering from pneumonia arising from exposure at the funeral of Professor Volkmann). At Spandau and Dantzic the disease has also appeared, so that any day we may expect its appearance in this country. Indeed, in Paris, where "la grippe" almost always prevails during the winter, there are many cases occurring in large establishments. Influenza is not wholly free from grave results in the case of the aged and infirm, and several fatal cases resulting from supervening pneumonia are reported from St. Petersburg. In this city, however, the epidemic would appear to be beginning to decline. It is remarked that the mean daily temperature during the month ending Nov. 27th was this year 34·5° F., whereas the average of the last 126 years was only 29·5°. The barometer was somewhat higher than usual, and there was a south wind during nineteen days, which is very unusual at this time of year. There is a considerable increase in the number of cases of catarrhal pneumonia following attacks of influenza. Besides, there seems to be an unusually large number of cases of croupous pneumonia.

DEATHS IN THE INDIAN MEDICAL SERVICE.

VERY recently the Indian medical service has experienced the loss of several medical officers of distinction.

Surgeon-General Edward Green Balfour, who has died at the age of seventy-eight, was an eminent officer of the Madras Medical Establishment. He was in the public service of India from 1834 to 1876—forty-two years. After being in medical charge of the native and European troops of all branches, he served from 1862 to 1870 in the administrative grade of the Madras Medical Staff as deputy surgeon-general in Burmah and the Straits Settlements, and for four years with the Hyderabad Subsidiary Force and Hyderabad Contingent. From 1871 to 1876 inclusive he was, as surgeon-general, the head of the Madras Medical Department. For many years he held appointments at the Court of the Nawab of the Carnatic. In 1850 he founded the Government Central Museum at Madras, and subsequently collected animals, which formed the nucleus of the Madras Zoological Gardens, in the People's Park. In 1866 he instituted the Mysore Museum. He was secretary to respectively the Madras Central Committee for the Great Exhibition, 1851, the Paris Exhibitions, 1855 and 1868, the International Exhibition of London, 1862, and the Vienna Exhibition, 1873. His literary productions on Indian subjects are well known, but his chief work was his "Cyclopædia of India and Southern Asia."

James Shaw, F.R.C.S., Principal Inspector-General of Hospitals, has died in his eighty-first year. He belonged to the Madras Medical Department, and during Lord Elphinstone's Presidency of the Government was surgeon to the Governor and the Governor's body-guard. He was subsequently appointed Government oculist, with the charge of the Eye Infirmary, which he held many years, and acquired a large private practice in Madras. He was the first principal of the Madras Medical School, when that institution became a college. He finally retired from the Indian Government service in 1867.

Surgeon-General John Turner, late of the Bombay Medical Service, has died at Bath, aged seventy-five. He served as surgeon, in the *Nemesis*, in China in 1841-42, was present at several attacks and campaigns there, and was awarded the medal for his services. He also served in campaigns under Sir Charles Napier, in 1845–46, and in 1858, under Sir Hugh Rose. For more than twenty years he was surgeon with the Horse Artillery, and for eight years principal medical officer at Aden, and subsequently appointed Inspector of Hospitals of the Northern Division of Bombay.

PHTHISIS IN HIGH ALTITUDES IN SWITZERLAND.

FROM a report by Dr. L. Schrötter on the distribution of phthisis in Switzerland it would seem that the inhabitants even of high altitudes are by no means so free from phthisis as we are perhaps wont to suppose. The tables of deaths for the eleven years 1876–1886 show that phthisis is endemic in every part of Switzerland, not a single district (Bezirk) being free from it. On the whole, the deaths from this cause are fewer in the high than in the low-lying districts, but it cannot be said that the mortality from this cause is inversely proportionate to the altitude. Wherever there is a large industrial population the phthisis mortality is considerable. Industrial populations always suffer much more than agricultural populations where the altitude is the same.

VENESECTION IN LEAD POISONING.

DR. WILHELMI of Güstrow strongly recommends that in cases of lead poisoning a small quantity of blood should be taken from the arm. He has practised this treatment in twenty-five cases, and speaks warmly of the success he has met with, the patients in some cases expressing themselves as greatly relieved immediately after the operation and the affection taking a marked change for the better from that time.

INTERMITTENT FEVER.

DR. ALOIS FÉNYKÖVY communicates to a Vienna medical journal an account of some observations made on the treatment of intermittent fever by means of friction of the back along the spine. Many years ago, while at Nisch with his regiment, there occurred so many cases of intermittent fever that the stock of quinine was becoming exhausted, and in order that the patients might not be entirely without some sort of treatment, it was ordered that they should be rubbed twice a day along the spine with simple ointment. The day after this order had been given it appeared that the usual attack had not come on; accordingly, since that time

Digitized by Google

Dr. Fénykövy has very frequently employed this treatment, and usually with marked success. Indeed, he says that three-fourths of his cases have done very well without any quinine at all.

THE HYDERABAD CHLOROFORM COMMISSION.

THE limited space available in a telegraphic message prevented Dr. Lauder Brunton from giving any details concerning his experiments upon chloroform, and it is altogether premature to argue a question still *sub judice*. We regret, therefore, that the lay press has, at least in one instance, jumped to a conclusion certainly unwarranted by the facts, as far they are at present before us. A sensational paragraph, telling the public that at length it is absolutely settled that chloroform kills by failure of respiration, and never through syncope, is certainly calculated to do harm. When a lay paper goes on glibly to observe that if the pulse is left alone and the respiration watched no danger can be incurred, we are reminded how perilous is "a little knowledge." It then becomes our duty to urge upon readers that the research which Dr. Lauder Brunton has undertaken is one not lightly dealt with, nor are conclusions to be formed until we have heard Dr. Brunton himself state to what results his experiments have led him. At present the whole question remains *in statu quo antea*. Nor must the issues be confused. There is another aspect of the question than that which up to the present time has engaged Dr. Brunton's attention—namely, the evidence arrived at by clinical observation. Bearing these facts in mind, it is evidently premature to offer any decided opinion as to the exact *modus operandi* of death under chloroform, and it would certainly be wholly unjustifiable to relax any of the precautions and care at present adopted by practical anæsthetists as necessary when dealing with chloroform.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—Dr. Klemperer has qualified as *privat-docent* in Medicine, and Dr. Nitze in Diseases of the Urinary Organs. Dr. Lassar has been appointed to give clinical instruction for Professor Lewin, who has not quite recovered from his illness.

Freiburg.—Dr. Sonntag has qualified as *privat-docent* in Midwifery and Gynæcology.

Leipsic.—Dr. Landerer has been promoted to the rank of Extraordinary Professor of Bandaging and the Use of Surgical Apparatus, and Dr. Tillmanns to be Extraordinary Professor of Surgery.

Moscow.—Dr. Kusmin has been placed on the staff as Extraordinary Professor of Surgery.

Padua.—Dr. Cervesato has been appointed Extraordinary Professor of Children's Diseases. Dr. P. Bonuzzi has qualified as *privat-docent* in Medical Pathology.

St. Petersburg (*Medico-Chirurgical Academy*).—The candidates for the chair of Clinical Surgery, rendered vacant by the death of Professor Bogdanovski, are Drs. Kruglevski, Multanovski, and Ratimoff.

AT the next meeting of the Neurological Society, to be held on Thursday, the 19th inst., at the National Hospital, Queen-square, Mr. James Sully, A.M., is, we see, announced to give an address on the Psycho-physical Process in Attention. The subject is one of much difficulty and interest, and also of much practical importance. We understand Mr. Sully will deal with the psychology of attention, and the psycho-physical experiments bearing on it. He will discuss the nervous process in attention, and its relation to motor innervation; and, lastly, he will deal with habitual directions of attention and interest, and the practical bearings of the subject.

PROFESSOR WESTPHAL of Berlin, who has been ill for some time, is, we are sorry to learn, worse, and it is thought unlikely that he will ever be able to resume the duties of his chair. The charge of his clinic is for the present being undertaken by Dr. Oppenheim.

AT an investiture of the Order of the Bath on the 5th inst. at Windsor, held by the Queen, Sir John Banks, Physician in Ordinary to the Queen, was invested with the Order of Knight Commander of the Bath.

THE publication of Sir Joseph Lister's paper, read at the Hunterian Society, has been deferred in consequence of some further investigations which have been found necessary.

MR. C. LEOPOLD HUDSON, F.R.C.S. Eng., has been appointed to the office of Surgical Registrar of the Middlesex Hospital, vacant by the resignation of Mr. W. Roger Williams.

THE cholera epidemic in and round Bagdad, which had a little abated about the middle of October, is stated to be now raging there more violently than ever.

THE LANCET AND THE HYDERABAD CHLOROFORM COMMISSION.

WE have received by mail a copy of the *Deccan Times* containing an interesting account of a banquet given in honour of the members of the Hyderabad Chloroform Commission by the Nawab Intesar Jung, on Tuesday, Nov. 12th. The dinner, to which 140 guests sat down, was given in the beautiful ball-room of the new Secunderabad Club, and left nothing to be desired as regarded the perfection of the arrangements and the quality of the viands. After the usual loyal toasts, the Nawab proposed the health of the Minister, Sir Asman Jah, who responded in the Urdu language, a translation of which was afterwards read by the Minister's secretary. The Minister, in proposing the health of the members of the Chloroform Commission, went into the history of the circumstances leading up to the appointment of the Commission with a view to settling once for all the vexed question of the attributes of chloroform. The Minister's concluding words were as follows:—"To enable Dr. Lawrie to bring about such an inquiry, his Highness was pleased to place a generous donation at his disposal, and the proposal being communicated to THE LANCET, perhaps the first medical journal of the world, the conductors of that periodical induced Dr. Lauder Brunton, whose name stands foremost in this branch of research, to go out as their representative. The Government of India has also been pleased to depute Surgeon-Major Bomford, a distinguished member of the Indian Medical Service, to assist at the conference. Experiments are performed daily at the Residency Medical School on dogs and monkeys, in which the effect of chloroform on the heart and on respiration is noted by means of instruments of marvellous delicacy, such as perhaps have never before been used in India. Now I venture to say that we Mohammedans are peculiarly entitled to sympathise with the objects of the Commission, for we were the first originators of that experimental research which in the hands of Europe has led to such magnificent results. The seed was sown by our ancestors, and nourished with the waters of the Euphrates and the Guadalquiver. Chloroform and ether, and some other wonderful agents, have been obtained from substances first discovered in the laboratories of a Razi, a Jubair, or an Ibu-i-Yunus. Mussulman surgeons were the first to make use of the actual cautery, and they invented instruments for midwifery and for ophthalmic surgery. Ibu-i-Haisum, known to Europe as Al Hazen, discovered the weight of the atmosphere, and fixed its height at fifty-two miles;

Digitized by Google

enunciated the principle of aberration in optics; and almost reconstructed that science on mathematical principles upon the scant foundation laid by the Greeks."

Dr. Lauder Brunton, on rising to reply, was greeted with loud and continued applause. The following is an abstract of Dr. Brunton's remarks:—"I cannot readily find words to express my sense of the honour that you, our host, have done to me and to the members of the Hyderabad Chloroform Commission in inviting us here to-night. My enjoyment to-night is alloyed by pain that I am unable adequately to express my sense of the generosity of the Nizam's Government, and of all the kindness shown to a stranger like myself since my arrival in Hyderabad; yet this pain enhances the pleasure which the undeserved and generous kindness affords. But the saddest thought with which our pleasure is mixed is one which is nevertheless itself the cause of our pleasure to-night—viz., that all over the world men and women and children are suffering from pain and calling for relief which it is not always in the power of medical art to afford. In the speech which you have just heard from our host, all the essential points in regard to anæsthetics have been so clearly put that it is quite unnecessary for me to say more about them; I may merely repeat that the questions which the Hyderabad Chloroform Commission has to settle are: Why do deaths occur during the administration of anæsthetics? How are they to be prevented? Some men are inclined to think that some such deaths are inevitable; whereas others, like my friend Surgeon-Major Lawrie, consider that they are quite preventable, and that anæsthetics (and especially chloroform) may be always administered with safety provided proper care be taken. This is a question upon the solution of which so much depends that for the last forty years or more men have been trying all over the world to solve it. But all this time Governments which would spend millions upon appliances for destroying life have shown a singular apathy regarding means of saving both life and suffering. It has been reserved for the Nizam and his able Minister Sir Asman Jah to appoint a commission specially to investigate the action of chloroform and solve, if possible, the important questions which I have just mentioned. As our host has said, there is a peculiar appropriateness in this appointment being made by the Nizam's Government as a great Mohammedan power, for in the middle ages, when the arts and sciences were almost lost in Europe, they still flourished at Bagdad and Cordova, and to the Saracens and Moors we owe the preservation of much medical lore which would otherwise have been lost. Especially did they direct their attention to the great practical point of the treatment of disease and the use of remedies, and in my own studies on the action of medicines I have had occasion to consult the works of Avicenna. Nor has the Nizam in the appointment of this commission followed the tradition of the Mussulmans only in the nature of the subject selected, for in the liberality with which he has carried out the scheme he has rivalled the generosity of Haroun-al-Raschid at Bagdad, and Abdulrahman at Cordova. I may perhaps be permitted to say that, although I have worked in laboratories in London, Edinburgh, Leipsic, Vienna, Berlin, Amsterdam, and Paris, and although no words can express my obligations to the directors of these laboratories for all the benefits I received at their hands, yet in none of them have I found the same facilities for work as at Hyderabad. For here we have all the apparatus required. Whenever anything is asked for it is at once supplied; dogs and monkeys on which to test the action of chloroform are provided in abundance, and of the willingness and ability of our assistants it would be impossible to speak in too high terms. By an improved method of recording our experiments we shall be able to render the records as readily available for examination and criticism by scientific men at the Antipodes as they are here, and a hundred years hence as they are now. As experiments are self-recording, they are also free from any possibility of the result being modified by a bias in the minds of the Commission, and whatever men may say to our conclusions it is impossible for them to challenge our facts. It may be hard in the space of a few weeks to settle a question that has remained without a certain answer for more than forty years, but, nevertheless, we hope that we shall be able to produce an array of facts such as shall carry conviction to the minds of all unprejudiced persons, and which, we trust, will be of such practical utility in helping to prevent suffering and preserve life, as to justify the great liberality of the Nizam's Government and lead other Governments to follow the noble example so generously set by that of the Nizam."

Dr. Lawrie, in a brief speech, explained that the work of the Commission was being carried on with perfect harmony, and with only one object in view—namely, to arrive at the truth.

ANNUAL REPORT OF THE LOCAL GOVERNMENT BOARD.

THE eighteenth annual report of the Local Government Board embodies for the first time an account of local government as reconstituted by the Local Government Act, 1888, and the resulting election of County Councils; and a somewhat lengthened account of the Act, of its results on our system of local government, and on the duties of various officers appointed under or affected by the Act, is included in the volume. Several important financial considerations bearing upon the Act are also considered. The question of pauperism is next dealt with; this question coming in somewhat inconveniently to break the continuity of the story of local government, which has again to be resumed when the question of local administration and public health is taken up as a third topic. There has, fortunately, been a further decrease in the amount of total pauperism; the decrease on that for the preceding year being at the rate of 1·7 per cent. There still remains, however, the uncomfortable fact that there is one pauper to every thirty-five persons in the population of England and Wales; and in the year ending Lady Day, 1889, the number of vagrants was larger than the mean number relieved in any recent year, except 1869, 1880, and 1881. The cost per head for paupers, which was £10 10*s.* 10½*d.* in 1888, somewhat exceeded that for the previous year, although it was less than for a number of previous years. Amongst the improvements affecting metropolitan Poor-law infirmaries, it is stated that changes are either being effected or are in prospect for the Lewisham, Woolwich, Greenwich, Whitechapel, St. Giles, Camberwell, and the St. Mary Abbots, Kensington, Unions. The fever cases admitted into the Metropolitan Asylums Board Hospitals during 1888 were 5152, as against 6537 in 1887; 88 per cent. being scarlet fever cases. The total number of admissions from small-pox were 62, a number small beyond precedent, and this although five years have elapsed since the last epidemic. During the year the Elberfeld system of poor law was investigated for the Board by Mr. J. S. Davy, the essential features of this system being three in number. The investigation of the circumstances of applicants for relief is undertaken by large numbers of unpaid almoners; the service of the almoners is not voluntary but compulsory; and the Poor-law authority consists of a small body selected and controlled by the Town Council, and not elected by the taxpayers. But it is not considered that such a system would work well in this country.

Reverting to local administration, as this term is generally understood, we find that the amount of loans sanctioned for urban and rural sanitary authorities has once more a slight tendency upwards, over two millions and a quarter having been thus taken up during 1888. Of this sum more than two millions were granted to urban authorities. Of the medical officers of health now holding office in the country, there was repayment of a moiety of the salary in the case of 1211 districts; the corresponding number for inspectors of nuisances being 1120; the total number of districts in England and Wales being 1004 urban and 574 rural, or 1578 in all. Among the defaulting sanitary authorities, Cheshunt has often been referred to; but it is now stated that the works of sewerage there have been completed, and that the writ of *mandamus* against the authority has been discharged. In several other instances works of a similar sort are impending with a view to the same result. Oundle in Northamptonshire and Fleetwood are two fresh cases that have recently been inquired into, and it seems clear that remedial action will have to be undertaken. Certain compulsory orders as to the removal of refuse were also issued during the year; and inquiries were held as to the pollution of a number of rivers. Steady progress is being made with the inspection of canal boats, and the indecent herding together of men, unmarried

Digitized by Google

women, and children in barge cabins has been much diminished, in some instances marriage settling the difficulty where the case was not complicated by some other condition, such as overcrowding.

Under the Sale of Food and Drugs Act there are now 52 analysts for counties and 184 for boroughs; and during 1888 the analyses, which were 26,344 in number, exceeded those for 1887 by about 1900. In London one sample was taken for every 551 persons; in the provinces there was one for every 1141. But there are great variations as to the amount of work carried out. Thus in Fulham the proportion was one sample to every 289 persons, whereas in Newington it was only one to every 7190. On the whole, substantial good is being effected. Thus in the five years 1878–82 the proportion of articles found to be adulterated was 15·5 per cent.; now it is 10·8. Unfortunately, the amount of fine imposed is insufficient to deal effectually with a traffic so remunerative as is, for example, that of watering milk, and though more care is taken in the fraudulent practice so as to avoid passing the wide variations in richness which milk in its natural state exhibits, yet the practice has by no means been put an end to. The average penalty was 27*s.*; the highest was £15. In one metropolitan district, where a sample of milk had been reported against, and where the chemists of the Inland Revenue Department had confirmed this verdict, the magistrates merely imposed a fine of 1*s.*, with 2*s.* costs. But the vestry, on the other hand, who had instituted the proceedings had to pay their costs, amounting to £3 9*s.* 2*d.*, they being in this way practically submitted to a heavy penalty for performing their duty towards the ratepayers. Another man who sold small quantities of milk-and-water to poor people as a food for their infants was also let off with a fine of 1*s.* Of the articles examined during 1888, the percentages of some of the principal adulterations detected were as follows: spirits, 17·9; lard, 16 8; coffee, 12·0; milk, 11·9; butter, 10·4; mustard, 9·5; pepper, 7 7; and drugs, 7·3. Fortunately, the adulteration of bread and flour grows less and less; and it is also stated that the sale of a mixture of fats as butter has received a decided check by the Margarine Act, 1887.

As to the report of Major-General A. de C. Scott, examiner under the Metropolis Water Act, it is stated that although the circumstances of the year were unfavourable to the filtration operations of the London Water Companies, yet a high standard of purity was maintained. The Kent Company stands alone in deriving all its supply from deep wells, and thus delivers its service unfiltered; indeed, the only drawback attaching to this water is a commercial one, for it is 50 per cent. harder than the rest of the London supplies, and as such it causes a needless waste of materials, such as soap. The number of houses receiving a constant supply increased during the past year by 41,006, and in this way many sources of pollution and a substantial risk to health are avoided.

A number of other matters are referred to in this report, which, as additional duties are cast upon the staff of the Local Government Board, tends to become more and more bulky. Some of these matters relate to the Board's medical administration for health purposes; but, as a separate report is soon expected to emanate from the Medical Officer of the Board on this subject, we postpone further reference to it for the present.

NEW MORTUARY AND POST-MORTEM ROOM AT THE MIDDLESEX HOSPITAL.

THE importance of having attached to every hospital a well-constructed mortuary and post-mortem room is generally recognised, but unfortunately in many instances the accommodation afforded leaves much to be desired. That pathologists and all who have to work in post-mortem rooms, frequently for hours together, should be able to discharge their duties with as little risk to their health as possible is of the first importance, and anyone who has had experience in hospital management will be able to appreciate the influence that a well-appointed mortuary exercises in smoothing over the difficulties that sentiment and prejudice too often place in the way of pathological research. The post-mortem room at the Middlesex has hitherto been in close proximity to the hospital, but the site being required for the erection of a chapel in memory of the late Mr. A. H. Ross an opportunity was afforded the authorities for carrying out a much-needed reform by providing the necessary accommodation detached from the hospital building.

Mr. Keith Young, the architect to the hospital, has designed and constructed a building, a short description of which may be of interest. Externally it is faced with red bricks and yellow terra cotta window mullions and dressings; the architecture is a simple form of classic, with round-headed arches to the doors and windows. The floors and the roof are constructed entirely of iron joists encased in concrete. The basement room is connected with the basement of the hospital by a subway, lined throughout with white glazed bricks, and ventilating into the open air. The floors of this subway, and of the room into which it leads are made of Portland cement and iron slag on a foundation of hard core. Above this room is the mortuary, standing on a level with the garden, and above the mortuary is the post-mortem room, to which access is gained by a separate stone staircase. The internal walls are lined throughout with glazed bricks, with the exception of the mortuary, where cream-coloured glazed tiles with a dark-green skirting are used. The floors of these rooms are marble mosaic. A hydraulic lift passes from the basement to the post-mortem room, and is worked direct from the main with a multiplying cylinder and piston arrangement instead of a ram. Accommodation has been provided in the basement for a destructor, in which it is proposed to destroy all the used dressings, together with anything else that it may be desirable to burn. The post-mortem room is so constructed that all the angles formed by the walls, and the floor and ceiling angles, are rounded so as to admit of being easily washed out. The tables are made of Belgian fossil marble, supported on cast-iron frames specially designed with a view to the avoidance of all angles. The drainage from the tables discharges into channel pipes in the floor, which are covered with open iron gratings. This channel, which leads into a lead pipe, properly trapped below and ventilating above the roof, can be flushed at pleasure by means of two six-gallon flushing cisterns, fixed to the walls. Hot and cold water are laid on to the sink and lavatory basins and over the centre of each table, and for the latter supply two mixing valves are provided by which the water can be regulated to any temperature desired. The ventilation of the mortuary is carried out partly by windows and two Tobin's tubes and partly by an exhaust shaft, which will, when the refuse cremator is erected, be heated by contact with iron plates forming the separation between the smoke flue of the cremator and the exhaust shaft. In the post-mortem room the large side windows and skylights, together with an open fireplace, afford efficient ventilation. Altogether the construction and general arrangement of this building are distinct advances, and will well repay a visit by anyone interested in such matters.

THE METROPOLITAN HOSPITAL SUNDAY FUND.

THE annual general meeting of the constituents of the Hospital Sunday Fund was held in the Egyptian Hall of the Mansion House on the 11th inst., at 3 P.M., and was well attended. The Lord Mayor, as president and treasurer, presided, and amongst those on the platform were the vice-president, Sir Sydney H. Waterlow, Bart., the Rev. Canon Fleming, the Chief Rabbi, Mr. A. L Cohen, Dr. Glover, and numerous other members of the Council. The secretary, Mr. Henry N. Custance, having read the notice convening the meeting, Sir Sydney Waterlow moved that the report of the Council for 1889 be received and approved. He congratulated them upon the growing success of the movement, the total receipts this year being over £1100 in excess of any previous year. He sincerely hoped that the subscriptions would continue to increase, and be worthy of the enormous population of this great metropolis. He was speaking the sentiments of the Council generally when he thanked those who made these collections for the suffering poor. Their thanks were specially due to Mr. Ernest A. Hankey for his noble contribution of £500, and he trusted that others would follow

Digitized by Google

that example. They were also specially indebted to the Rev. Prebendary Forrest and to the Rev. Canon Fleming for the large collections made amongst their respective congregations. He referred to the sum of £2000, being 5 per cent. of the total collection, set aside for the purchase of surgical appliances, and went on to show how satisfactorily and beneficially the plan had worked. During the past year complaints had been made as to some of the hospitals, and it had been said that the Distribution Committee, in advising the Council, had not had the courage to refuse a grant when they knew the institution to be undeserving. They did not pretend to criticise the system and policy of every hospital and institution. To do so would be to raise a host of enemies. But when they found a hospital or dispensary carrying on its work in a form which they thought the constituents would not approve, they first lessened the award, and then, if the evils were not remedied, removed the institution from the list altogether. They would find from the report that two institutions had been so removed, while others had been compelled to accept the reduced grant. He thought that the public might accept the decision of the committee in a case where a grant had been refused as an indication that the institution ought not to be supported.—The Rev. E. E. Jenkins seconded the motion. He sincerely wished that the operations and funds of the Society would extend year by year, and that eventually there would be no hospital that would not share in the benefits of the fund.—The Rev. Mr. Hall asked for information regarding the working expenses, which he thought compared unfavourably with previous reports. It seemed to him that £1400 was a large sum to pay for collecting £43,000.—Sir Sidney Waterlow expressed his pleasure at being asked the question, for such questions showed that an interest was being taken in the work, and helped to elicit facts. The increase in the working expenses was accounted for by the fact that they had had to find a new home for themselves, the Mansion House being no longer available. A new office had accordingly been opened in Queen Victoria-street. He could assure Mr. Hall that the work was continuous day by day all the year round. There were at least fifty letters daily to answer, besides shoals of applications for surgical appliances &c. to be dealt with. He could furthermore say that the Fund had never lost a farthing by any robbery or any fault whatever. — The report was unanimously adopted. — Resolutions were then put and carried: 1. "That the laws of the constitution which have been in force during the past year be continued." 2. "That the Council for the year 1889, with the Rev. Henry Douthwaite in place of the Rev. W. G. Pascoe, who has left London, be re-elected for the year 1890, and that Sir James Whitehead, Bart., the late Lord Mayor, be elected to the seat he formerly occupied." 3. "That the 8th day of June be fixed for Hospital Sunday of 1890, and that the cordial co-operation of all ministers of religion within the metropolitan area be again invited in the usual way."

The proceedings concluded with a vote of thanks for presiding to the Lord Mayor, who promised to do all in his power to make Hospital Sunday in 1890 a success.

THE BRITISH NURSES' ASSOCIATION.

THE Princes' Hall and the Galleries of the Institute of Painters in Water Colours, Piccadilly, presented a brilliant spectacle on Friday evening (Dec. 6th), on the occasion of the second annual conversazione of the British Nurses' Association, which has now over 2000 members in active work as nurses throughout the United Kingdom, in addition to many of the leaders of the medical profession, at least half the matrons of English hospitals, and a large number of midwives. We may here recapitulate the objects of the Association, which are twofold—viz., to increase the usefulness of trained nurses to the public and the medical profession, by elevating the general standard of their knowledge and efficiency; and by union to enable these workers to help each other in times of need. The first part of this programme has now been commenced by the formation of a representative Council, to undertake at once the work of registration of trained nurses. The register published annually will enable the public to discover whether any given woman who terms herself a certificated nurse is actually so or not. Hitherto there has been no means of preventing large numbers of untrained women from pretending to act in this capacity, and by their ignorance causing incalculable danger and suffering to the sick. To carry out its second object, the Association hopes shortly to be able to provide nurses with a convalescent home, when they themselves, as frequently happens, are rendered ill by attendance on others; and, in future, with holiday houses at seaside or country resorts, to allow many who could not otherwise afford it, the change of air and scene their arduous work makes essential for them. It also desires to found a benevolent fund to assist nurses when out of employment or in need from other causes.

In the absence of the President of the Association, Princess Christian, who, we regret to say, has been compelled to remain for the present at Wiesbaden, to undergo treatment for an ophthalmic complaint, the guests, who could not have numbered less than 1100, and many of whom came from distant parts of the country to spend an evening with their metropolitan sisters, were received by the Vice-chairmen of the Executive Committee, Sir Dyce Duckworth, Treasurer of the Royal College of Physicians of London, Mr. Pickering Pick (Surgeon to St. George's Hospital), and Miss Thorold (matron of the Middlesex Hospital). A pleasant hour was spent in the galleries inspecting the pictures and in the exchange of greetings between those who had not met since the inaugural conversazione twelve months ago, the attractiveness of the scene being enhanced by the rendering, under the experienced direction of Mr. J. Pougher, of a selection of popular music by the "Bijou" orchestra. The company subsequently assembled in the Princes' Hall, where an excellent ballad concert was given by Mrs. Stanley Stubbs, Mrs. Hancock, Miss E. Nesbit, and Mr. J. Robertson. This was followed by a laughter-provoking musical sketch, kindly given by Mr. Corney Grain, who, to judge by the reception accorded him, is an old favourite of the nurses. The closely packed audience presented a striking and unique *coup d'œil*, the white caps of the nurses resembling nothing so much as a field of snow, relieved, however, by the dresses representative of the different institutions, the sober black gowns of the district nurses standing out in charming contrast to the pink (Great Ormond-street), grey (Victoria Hospital), blue (St. John's House), and other colours and shades too numerous to mention. It was long past midnight before the last farewells were exchanged and the nurses separated, all to meet again, it is to be hoped, and spend a similarly enjoyable evening next year. It is reported that by means of paying tickets, issued to members' friends, the large cost of the gathering has been more than covered—a fact which is most significant of the ability with which the affairs of the young Association are being conducted. Great praise is due to the members of the Executive Committee, especially to Dr. and Mrs. Bedford Fenwick, and to the well-known Secretary, Miss Catherine Jane Wood, to whose combined exertions the complete success of the conversazione was largely due.

HEALTH OF THE IMPERIAL NAVY OF JAPAN.

THE health of the Japanese Navy continues to maintain the favourable condition brought about by the sanitary improvements effected in 1884. The report of Mr. Takaki Kanehiro, the Director-General of the Medical Department, shows the average strength to have been 9148, the cases occurring during the year to have been 3452, the deaths from all causes 65, the numbers invalided 84, and the constantly non-effective from sickness 288·52. These give the proportion of 377 admissions, 7·1 deaths, 9·18 invalided, and 31·54 mean sick per 1000 of strength. The admissions and mean sick are lower, but the deaths and invaliding higher than in the preceding year, but the excess is not greater than might be reasonably expected to occur in limited numbers. Of the deaths, 21 were from violence and accidents, leaving 44 by disease, or only 4·81 per 1000 of strength. Of the violent deaths 12 were by drowning (8 of which occurred from the capsising of a boat in Yokosako Bay), 3 from accidents, and 5 by suicide. Of the deaths by disease, 20 were caused by pulmonary affections, including 10 of phthisis, and 7 by

Digitized by Google

fevers, 5 of which were by enteric fever. There were 48 cases of this form of fever under treatment, so that the deaths amounted to nearly 1 in 10, which is a low proportion. It appears to have prevailed chiefly in two ships: the *Takachiho* in Taketayo harbour had 10 cases and 2 deaths, and the *Hiei* had 24 cases, of which 2 died. The *Takachiho* had also 3 cases of cholera with 1 death; the disease did not occur in any other ship. There was an epidemic of mumps, of which 129 cases were admitted on board five ships and in the barracks at Yokosuka and Uraya. The most prevalent diseases were syphilis and gonorrhœa; of the former there were 519 and of the latter 426 cases, together giving a ratio of 103 per 1000 of the strength, or 27 per cent. of the whole admissions. Eye diseases were also prevalent, there having been 178 cases of conjunctivitis, or 19·5 per 1000 of strength. No case of beri-beri occurred during the year, thus showing the continued immunity from it, which resulted from the improved feeding of the men introduced in 1884. This fact deserves the attention of the colonial medical staff at Hong Kong. There have been some unimportant alterations in the dietary during the year, chiefly a slight reduction in the amount of rice, barley, and pickles, and a corresponding increase in bread, vegetables, and milk.

Of 1338 applicants for admission to the navy as seamen, 1034 were rejected, or 773 per 1000. Of these, 539 were rejected for "badness of physical condition," but this term included 363 deficient in stature, and 495 were rejected on account of disease, 206 of these having skin diseases. In the appendix, the table showing the physical condition of the recruits has been reproduced, with additions, for the last two years, but does not include those of 1888. We would also point out that the strength in the table on page 8 does not correspond with that stated in the letter-press, and that the addition of the figures in the first column is incorrect.

IMPROVED FACILITIES FOR INVALID TRAVELLING BY RAIL AND SEA.

THE CLUB TRAIN.

(FROM OUR SPECIAL CORRESPONDENT.)

Improved Facilities for Patients Travelling to the Continent. —The Warming and Ventilation of Saloon Cars.—Special and Reserved Railway Accommodation.

AMONG the many permanent benefits resulting from the Paris Universal Exhibition, the notable improvement in the means of communication between England and France will be especially welcome to the ever-increasing crowd of travellers that yearly pass from one country to the other. Not many years ago the French ports could only be reached in very small steamers that seemed constructed for the purpose of producing the maximum amount of sea-sickness with the smoothest sea and in the shortest possible time. But now on all the three principal routes—the Calais, the Boulogne, and the Dieppe lines—there are fine ocean-going steamers that travel much more rapidly and steadily, and afford better cabin and deck accommodation to passengers. The most notable and most recent improvements have been accomplished on the Calais and Dover line. Here there are steamers that have succeeded in crossing the Channel in sixty-five minutes, with the accompaniment of the newest and most luxurious of all means of travel, the Club Train. Agreeable as this may be to the general public, it is of life-saving importance to the invalid. The principal drawbacks to wintering abroad have always been the fatigue, the exposure, and the hardships of the journey. But this danger and inconvenience have now been notably mitigated. It may safely be said that the great majority of travellers stand in "bodily fear" (to use a police-court term) of sea-sickness. The hale and hearty may face this contingency, and a little sea-sickness may prove a wholesome, though unpleasant, experience; but the weak, and patients suffering from organic disease, cannot brook the wear and fatigue of such drastic treatment. Consequently, the majority of patients, and even of the general public, select the shortest sea route. But the very shortness of the distance augments its terrors, for here the sea is most cramped by the land on either side, and it is precisely in the narrowest part of the Channel that the movement of the waters becomes so irregular and "choppy" as to readily produce sea-sickness. It is not so much the size as the peculiar formation of the waves that upsets even persons who have endured long journeys on the open ocean. Under these circumstances, the construction of larger and swifter vessels becomes a double blessing, for we have less motion and a quicker passage. Formerly, to cross from Dover to Calais it was necessary to travel by night, or to start at an inconveniently early hour in the morning; and in both cases the crossing was effected in a very small ship, which took a good hour and three-quarters to effect the passage. Now there are four trains both ways instead of two. The night passage is effected in the small steamers. The first train, at 8.40 A.M., corresponds with the *Invicta*, a ship which is particularly steady at sea, and can cross the Channel in an hour and twenty minutes. The arrival of this vessel at Calais is timed to meet the largest number of trains proceeding to all parts of Europe. The next departure from London is, however, more convenient, and is patronised by the largest number of passengers. The train starts at 11 A.M., connecting with the three magnificent new steamers, the *Empress*, the *Victoria*, and the *New Calais-Douvres*, which can cross in an hour and five minutes. These same ships serve for the Club Train, and it is only the night train, that leaves London at 8.15, which connects with the old and small boats.

Undoubtedly the invalid, for whom special precautions are necessary, will, if possible, take the Club Train. This will necessitate an extra outlay, over and above the first-class fare, of 16*s.*; or, if the place be booked beforehand, of 18*s.* 6*d.* The Club Train starts both from Charing-cross and Victoria Stations at 3.15 P.M., and consists of luxurious saloon carriages that communicate one with another, enabling the passenger to walk the whole length of the train. A very soft and springy carpet deadens the vibrations, and adds to the warmth and comfort of the saloons. Before the arm-chair seats there are tables, so that reading &c. may more easily be enjoyed. One of the cars is fitted up as a smoking saloon, and there are ladies' and gentlemen's lavatories attached to each car. The central car is divided into small compartments containing two or four places in each. Here the invalid may lie down unobserved by the rest of the passengers, and here also the medical attendant would be more at ease in administering to the wants of his patient. Further, it would be easier to maintain a given temperature in one of these separate compartments than in the general saloon. The heat is supplied by hot water coils fitted round the sides of all the carriages; and in a very small compartment, where the attendant sits, there is a small coke stove for this purpose. It must, however, be acknowledged that in respect of the warming and the corresponding problem of the ventilation of the carriages there is still much room for improvement. The service is quite new and evidently this question has not been taken thoroughly in hand. On questioning several of the attendants, it became quite clear that they had no distinct plan, no definite instructions. At Charing-cross one of the attendants said he kept his carriages warmed up to 70°F., and certainly, though it was freezing at the time, they were very hot. On investigating the matter more fully, I found, however, that the thermometer was suspended in the little compartment where the stove is placed, and there certainly the temperature was at 70°, and might have been much higher; but this did not represent the temperature of the saloons where the passengers sat.

However carefully the train may be warmed before the arrival of the passengers, the opening and shutting of the doors, the delay in handing in parcels and rugs, the eager opening of windows for a last word or a final shake of the hand with some friend on the platform, soon defeat the most careful precautions and entirely alter a previously prepared temperature. Thus, a day later, while it was still freezing, the temperature in the saloon of the Victoria Station Club Train had fallen, when the time of departure arrived, to 45°F. On the platform of the station Steward's thermometer recorded 34°, so that the inside of the train was only eleven degrees warmer than the platform. This is not surprising considering the long time the carriage doors were kept open, particularly as it was by this same train that the Hon. Mrs. Robert Bruce was starting for Monte Carlo when she was seized by a fatal syncope. Of course this catastrophe occasioned some confusion, and as the

Digitized by Google

unfortunate lady had to be carried out of the carriage, the doors were probably kept open for a much longer time than usual. From one cause or another it must often happen that the carriages will become exceptionally cold, and this would not so much matter if the fact were known, watched, and corrected immediately. But in the train in question the attendants had no thermometer whatever, and, no complaints being made, were not aware that anything abnormal had occurred. With Immisch's pocket and clinical thermometer, after ascertaining that the temperature in the saloon had fallen to 45°, I proceeded to take the temperature of the smoking saloon, and found it to be 55°. Evidently there had been less cause of disturbance in this part of the train. Had the attendants been on the watch for such variations these defects might have easily been remedied. As it was, in the absence of thermometers and of proper instruction, the temperature of the saloon during the whole of the journey to Dover barely rose to 50°, while that of the smoking saloon never fell below 55°. Every carriage should have at least one thermometer, and these the attendants should watch and never allow to fall below a minimum, which might be varied according to the season of the year. With a little care, by watching both the doors and the thermometer the temperature within the saloon need not have fallen so low even on this freezing day, and might certainly have been promptly raised again to a degree more agreeable to the patients who were travelling in the train.

The matter of ventilation is not so easily arranged. The centre of the carriage roof is slightly raised, forming a sort of elongated lantern. On each side there are small windows that open inwards from the top, so that the air entering is thrown upwards, is broken up against the ceiling, and thence deflected into the carriage. Thus the direct draught is avoided. The objection to this very simple device is that its efficacy is at the mercy of the caprice or the neglect of the attendants and the passengers. The latter are rarely agreed on such points. The one desires to open a great number of ventilators, and glories in a plentiful supply of air; the other is in dread of draughts, and very liable to chills. Apart, then, from such means as are subject to the whims and fancies of the travellers, it would be desirable that fresh air should be automatically and regularly supplied to the carriages. This, of course, is done accidentally, though to an unknown and unreliable extent, by the cracks and chinks of the doors &c., and the possible porosity of some of the material with which the carriages are built. But such fortuitous ventilation is not worthy of this scientific age. Perhaps the little compartment where the stove stands might be utilised as a mixing room, where hot and cold air could be blended previously to admission into the saloon cars. In any case, something yet remains to be done in this direction. By such means travelling will be rendered much more agreeable to all, and much less dangerous to the weak and infirm. Yet these benefits, though of so extended a character, will involve little or no extra expense. More science in the methods employed, and more care and intelligence in their application, are undoubtedly necessary, but this does not necessitate any financial expenditure worth mentioning.

Apart from the saloons, the Club Train has a special compartment where on the return journey to London the luggage which has come from the Continent is examined as the train proceeds. This is a very material advantage. Not only is it a great saving of time, but the risk of sudden exposure to the draughts and changes of temperature between the train, the platform, and the Custom House Offices is avoided, as well as the hurry and worry of the examination. This being done in the train itself, there is plenty of time and no need for any anxiety. The same convenience is provided in the French train which meets the boat as it arrives at Calais. There the luggage is examined during the course of the journey to Paris. At Calais not a moment is lost. The train can be started about five minutes after the boat arrives. The passengers are not as a rule very numerous, so that the luggage is soon transferred from the boat to the train. The passengers have no cause to go into the railway station. There is a restaurant carriage in the train, and a *table d'hôte* dinner is served shortly after the departure from Calais—namely, at 7 P.M. The train reaches Paris at 11.15 P.M., where, the luggage having been examined in the car, the passenger has nothing to do but to drive to his home or hotel, and may hope to be comfortably in bed by midnight. Thus the traveller who has lunched in London, who has been in the Strand at three o'clock, and has crossed the Thames some few minutes later, will find himself, in seven hours and three-quarters, by the banks of the Seine and in full view of the Paris Boulevards.

Both with respect to the Club Train and the other trains, the Chatham and Dover Railway Company are very ready to give whatever assistance is within their power to invalids and others requiring special care. By communicating with the company, compartments can be reserved both on the English and the French side, and the agents of the company are ready to meet passengers at the landing stage and tender every sort of help needed. For instance, I saw a paralysed lady taken from the boat and laid down in a reserved compartment of the French train at Calais without any difficulty whatever. There is at Calais a body of porters called *les rouleurs*, who are admirably organised. They are kept under the strictest discipline by a self-elected captain, and form a very close society. To be admitted into this corporation it is necessary to possess exceptional strength and agility, and also to pay a deposit of £40. All sums of money received must be given over to the common fund. The receipts are divided among the members of the Association, and thus there is no unseemly squabbling or rivalry between the men to obtain the most remunerative jobs. It would be difficult to find anywhere a more reliable and a more steady set of men. With or without the invalid chair they easily carry patients in and out of the trains or the boats, and the fact that the services of such well-organised porters may always be counted upon greatly augments the facilities of the journey. As an illustration of the trouble the company will take to satisfy the desires of travellers, a lady patient wrote some time ago that she wished to proceed from London to the Riviera, but would only venture on the journey if a hammock was provided for her the whole way. Consequently a hammock was slung in a cabin specially fitted up for the purpose. A compartment of the French train had to be altered, and a hammock fixed in it in the same manner. But this was not all. The lady insisted that she would not travel in the train unless her hammock was fixed in the last carriage but one. The French Northern Railway Company has shown itself in all these circumstances most courteous and ready to meet the demands addressed to them by the agents of the Chatham and Dover Company. In this case, therefore, particular care was taken that the hammock and the carriage in which it was placed should occupy precisely the portion of the train desired by the passenger. What is perhaps a still greater strain on the obliging disposition of both the English and French companies is the fact that many intending passengers write and make all manner of arrangements, and then, at the last moment, alter all their plans or postpone their journey. The ordinary French trains that meet the two day boats have a small saloon with four places and a lavatory, which can be secured by paying 4 francs 40 centimes above the first-class fare for each place; and though this does not offer the luxuriousness and roominess of the Club Train, still this little saloon compartment contains what is essential to the proper comfort and care of a patient. In all these circumstances, however, considering that the accommodation must necessarily be limited, and that it is impossible to foresee precisely how many passengers may come by any one train, it is indispensable to write beforehand so as to make sure that the required seats &c. shall be reserved. Of course, in all this I only allude to invalids or delicate persons who cannot safely encounter the little hardships and accidental inconveniences which the young and robust often regard as adding to the charms of travelling. In a subsequent letter I will describe how the facilities of communication between London and the Continent have also been developed by the remarkable improvements of the Port of Calais, and will endeavour to show that the wonderful augmentation of English traffic and the increased number of English residents in that town must make us feel a growing interest in all that relates to its progress and prosperity.

Calais, December, 1889.

THE HEALTH OF CEYLON has not been satisfactory of late, fevers of a malarial type and cholera having prevailed in several parts of the island. One of the most serious outbreaks occurred among the pilgrims to the Roman Catholic shrine at St. Anna's, scaring the pilgrims, who quickly dispersed, carrying the infection with them.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5354 births and 3040 deaths were registered during the week ending Dec. 7th. The annual rate of mortality in these towns, which had been 19·2 and 19·0 per 1000 in the preceding two weeks, further rose last week to 21·5. During the first ten weeks of the current quarter the death-rate in these towns averaged 18·4 per 1000, and was 2·6 below the mean rate in the corresponding periods of the ten years 1879-88. The lowest rates in these towns last week were 14·2 in Birkenhead, 16·7 in Brighton, 17·5 in Nottingham, and 18·0 in Leicester. The rates in the other towns ranged upwards to 29·4 in Salford, 29·6 in Hull, 30·4 in Sunderland, 30·7 in Bolton, and 36·7 in Plymouth. The deaths referred to the principal zymotic diseases, which had been 339 and 243 in the preceding two weeks, rose last week to 363; they included 87 from measles, 87 from whooping-cough, 70 from scarlet fever, 67 from diphtheria, 39 from "fever" (principally enteric), and not one from small-pox. These zymotic diseases caused the lowest death-rates during the week in Leicester and Brighton; and the highest rates in Salford, Bolton, and Plymouth. The greatest mortality from measles occurred in Wolverhampton, Nottingham, Sunderland, and Norwich; from whooping-cough in Wolverhampton, Hull, and Bolton; from scarlet fever in Blackburn and Plymouth; and from "fever" in Preston, Birkenhead, and Halifax. The 67 deaths from diphtheria in the twenty-eight towns included 47 in London, 3 in Salford, 2 in Liverpool, 2 in Preston, 2 in Sheffield, and 2 of Newcastle-upon-Tyne. Small-pox caused no death in any of the twenty-eight great towns. Only one small-pox patient was under treatment in the Fever Hospitals of the Metropolitan Asylum Hospitals, and one in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and London Fever Hospitals at the end of the week was 1663, against numbers increasing in the preceding twenty-three weeks from 509 to 1650; 154 cases were admitted to these hospitals during the week, against 152 and 182 in the preceding two weeks. The deaths referred to diseases of the respiratory organs, which had increased in the previous six weeks from 261 to 345, further rose last week to 432, but were 33 below the corrected average. The cause of 23, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Sunderland, Portsmouth, and in five other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Norwich, Bristol, and Preston.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the preceding four weeks from 19·8 to 21·0 per 1000, further rose to 23·9 in the week ending Dec. 7th; this rate exceeded by 2·4 the rate that prevailed during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 18·0 and 19·7 in Aberdeen and Dundee, to 26·5 in Leith and 26·6 in Paisley. The 612 deaths in the eight towns showed a further increase of 76 upon the numbers returned in recent weeks, and included 30 which were referred to whooping-cough, 13 to scarlet fever, 11 to measles, 4 to diphtheria, 4 to "fever" (typhus, enteric, or ill-defined), and not one to small-pox; in all, 67 deaths resulted from these principal zymotic diseases, against 53 and 81 in the preceding two weeks. These 67 deaths were equal to an annual rate of 2·6 per 1000, which exceeded by 0·6 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 7 and 21 in the preceding two weeks, were last week 30, of which 9 occurred in Glasgow, 8 in Edinburgh, and 2 in Greenock. The 13 deaths from scarlet fever corresponding with the number in the previous week, and included 8 in Leith and 3 in Glasgow. The 11 fatal cases of measles showed a decline of 7 from the number in the previous week; 7 were returned in Edinburgh and 3 in Glasgow. The 10 deaths attributed to diarrhœa showed a further decline from recent weekly numbers. The 9 deaths from diphtheria corresponded with the number in the previous week, and included 3 in Glasgow, 2 in Greenock, and 2 in Paisley. Of the 4 deaths referred to "fever" 2 occurred in Greenock. The deaths from acute diseases of the respiratory organs in the eight towns, which had been 149, 135, and 121 in the preceding three weeks, rose last week to 166, and exceeded the number in the corresponding week of last year by 46. The causes of 80, or more than 13 per cent., of the deaths registered in the eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·2 and 28·7 per 1000 in the preceding two weeks, declined again to 27·6 in the week ending Dec. 7th. During the first ten weeks of the current quarter the death-rate in the city averaged 25·8 per 1000, the mean rate during the same period in 76 large English towns was 19·2, and in Edinburgh 20·1. The 188 deaths in Dublin showed a decline of 6 from the number in the previous week; they included 12 which were referred to "fever" (typhus, enteric, or ill-defined), 3 to whooping-cough, 2 to diarrhœa, 2 to measles, 1 to diphtheria, and not one either to small-pox or scarlet fever. Thus the deaths from these principal zymotic diseases, which had been 14, 9, and 26 in the previous three weeks, was last week 21; they were equal to an annual rate of 3·1 per 1000, the rate from the same diseases being 2·2 in London and 3·7 in Edinburgh. The deaths referred to "fever," which had been 6 and 11 in the previous two weeks, further rose last week to 12; whereas the fatal cases of whooping-cough, diarrhœa, and measles showed a decline from the numbers in the previous week. The deaths of infants showed a considerable increase, while those of elderly persons were fewer by 5 than the number in the previous week. Five inquest cases and 3 deaths from violence were registered; and 57, or more than a quarter, of the deaths occurred in public institutions. The causes of 30, or 16 per cent., of the deaths in the city were not certified.

THE SERVICES.

ARMY MEDICAL RESERVE OF OFFICERS.—Surgeon-Major Alexander Ramey Leith Napier, M.D., resigns his commission (dated Dec. 11th, 1889); Acting Surgeon John Joseph Ardaven Vincent Constantine Bayly, 1st City of London Artillery Volunteers, to be Surgeon, ranking as Captain (dated Dec. 11th, 1889).

INDIA OFFICE.—The Queen has approved of the following promotions made by the Governments in India:—Bengal Medical Establishment: Surgeon-Major George Thomson to be Deputy Surgeon General (dated Oct. 1st, 1889); Surgeons Hugh Thomson, Hem Chunder Chatterjee, and Ezekiel Salisbury Brander, Pakir Chundra Chatterjee, and George Augustus Evanson to be Surgeons-Major (all dated Oct. 1st, 1889).—Madras Medical Establishment: Surgeon Charles Henry Bennett, M.D., Surgeon William Henry Thornhill, M.D., and Surgeon Manockjee Eduljee Reporter to be Surgeons-Major (all dated Oct. 1st, 1889).—Bombay Medical Establishment: Surgeons Robert Manser, Henry Adey, Alfred William Frederick Street, D.S.O., Henry Prue Jervis, David Charles Davidson, James Charles Harding Peacock, Kaikhosro Sorabji Nariman, and Arthur Francis Sargent to be Surgeons-Major (all dated Oct. 1st, 1889).

YEOMANRY CAVALRY.—Hampshire (Carabineers): Geo. Fuller Ambridge England, M.B., to be Acting Surgeon (dated Dec. 7th, 1889).

ADMIRALTY.—The following appointments have been made:—Alexander Turnbull, M.D., Deputy Inspector of Hospitals, to Plymouth Hospital, and Henry F. Norbury, M.D., C.B., Deputy Inspector of Hospitals, to the Medical Department of the Admiralty (both dated Jan. 1st, 1890); Staff Surgeon James L. Sweetnam, M.D., to Nankin (dated Dec. 19th, 1889); Fleet Surgeon Robt. Hay to Haslar Hospital, temporarily (dated Dec. 21st, 1889); Fleet Surgeon Thomas Bolster to the *Camperdown*, Staff Surgeon Albert C. Queely to the *Esplendor*, Surgeon John Neil Tomkins to the *Camperdown* (all dated Dec. 19th, 1889); and Mr. Duncan Gunter Macdonald to be Surgeon and Agent at Holbeugh (dated Dec. 6th, 1889).

VOLUNTEER CORPS.—*Artillery*: 1st London (City of London): Acting Surgeon J. J. A. V. C. Bayo to be Surgeon

Digitized by Google

(dated Dec. 7th, 1889).—*Royal Engineers* (Fortress and Railway Forces): 2nd Lanarkshire (the St. Helen's): Surgeon E. F. Hall, M.D., to be Surgeon-Major, ranking as Major (dated Dec. 7th, 1889).—*Rifle:* 7th (Clackmannan and Kinross) Volunteer Battalion, Princess Louise's (Argyll and Sutherland Highlanders): Thomas Milne, M.D., to be Acting Surgeon (dated Dec. 7th, 1889).

NURSING SISTERS IN THE ARMY.—A Royal Warrant has been issued by the Secretary for War directing that in future candidates must be over twenty-five and under thirty-five years of age, and have had at least three years' preliminary training and service in a civil hospital. They are not to continue in the service after reaching the age of sixty.

COLOUR TESTS FOR RAILWAY SERVANTS.

To the Editors of THE LANCET.

SIRS,—As it appears that this subject has recently caused and is still causing some discussion both in the lay and medical press, and that none of the tests hitherto proposed seem to satisfy all parties, I should feel obliged if you would kindly allow me to describe a simple piece of apparatus which I constructed some time ago, and with which I have tested several drivers and guards. The point to be ascertained really is, "Can drivers and guards readily distinguish red and green lights under varying conditions of the atmosphere at distances ranging roughly from fifty yards to a mile"? That a man can recognise a mass of red or a mass of green placed close to him goes for little. The area of illumination of a lamp, as it appears to us, is inversely proportionate to the square of its distance from us; and therefore by placing immediately in front of a coloured lamp fixed, say, six yards from us a screen perforated with different-sized apertures, we can mathematically reproduce the effect of a lamp of a given size at different distances; and this is the principle on which my test is based. A man examined by this method is placed under (practically) exactly the same conditions as if he were taken out on to the line and asked to look at different signal lights—some near, some far off, and some in groups. It should be borne in mind that heavy smokers—and I think I am not wrong in assuming that engine-drivers consume a good deal of tobacco—sometimes become the subjects of a central scotoma, with a corresponding amount of colour-blindness; so that central coloured rays (such as those emanating from a six-inch lamp at 800 yards), which would be focused at a point corresponding to the affected region of the fundus, would not be recognised, though the rays from the same lamp held only a few yards off would be judged quite correctly, as they would then impinge on more *peripheral* portions of the retina. My instrument consists essentially of a lamp contained in a light-tight lantern, having in it a circular aperture one inch in diameter. About two inches in front of this aperture is a metal screen six inches square, also pierced with a corresponding hole of the same size as that in the lantern. Between the screen and the lantern (and attached to the former) is a brass carrier holding a red and a green glass, and so arranged that either may at will be placed in the field by a slight movement of the finger of the operator. In front of the screen is a metal disc, with a number of holes of different sizes bored through it, and disposed at equal distances near its margin. On rotating the disc the holes are brought one after another opposite the illuminated area, and act like "stops" in a photographic lens. The result of this is to limit the "coloured light" seen by the examinee to the size of the apertures in the disc, and to represent to his eye a lamp of a given size at successively increasing or decreasing distances. The red and green glasses are changed about each time at the operator's pleasure. One segment of the disc is devoted to another phase of the test, and is perforated with groups of holes in various relations to each other. These are supposed to represent tail lights of distant trains. The examinee must be able to see not only their colour, but also their number and positions. Finally, a second disc is placed in front of the first, and is fitted with a series of neutral tint glasses of different intensities, to present the appearance of various degrees of fog. The whole apparatus stands in a dark room on a level with, and at a distance of six yards from, the examinee's eyes, which are each tested separately. I think if Mr. Stretton were to see my arrangement he would be satisfied that the test is a fair one.

I shall be happy to allow any gentleman interested in the subject an opportunity of inspecting the test if he will communicate with me. Meanwhile I shall be glad to receive any expression of opinion on the method I have so imperfectly described.

I am, Sirs, yours obediently,

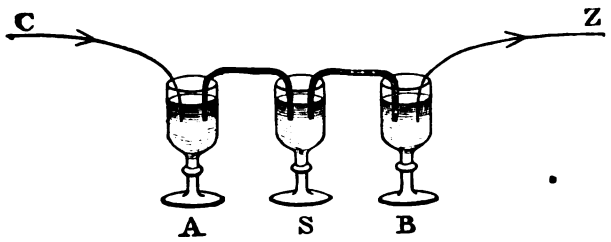
Seymour-street, W., Dec. 10th, 1889. A. ST. CLAIR BUXTON.

To the Editors of THE LANCET.

SIRS,—I admit the advantage which would be gained by using lamps with coloured glasses in testing colour vision, but these are obviously not readily used in a consulting-room. If the railway companies were willing to appoint someone on purpose to test the vision of their *employés*, lamps, railway signals, high and low lights in various combinations and distances might be used. Until this or some similar method is adopted I am not without hope that my instrument, simple though it be, may prove of use to the railway surgeon as a practical test for colour-blindness in railway *employés*. From men working practically on railways I learn that the distance the lights can be distinguished so as to recognise what train is advancing or receding, and whether it is a mail, a slow, or goods train, varies from over a mile to twenty or thirty yards. These facts alone are, I think, sufficient to show that any system which involves the use of railway lamps as a test for colour vision, to be of real service for these varying distances for different combinations of lights, would absorb almost all the time of a person experienced in testing for errors in refraction, colour vision, or visual acuity.

I am, Sirs, yours faithfully,

Carlisle, Dec. 9th, 1889. H. A. LEDIARD.



THE TREATMENT OF CANCER BY ELECTRICITY.

To the Editors of THE LANCET.

SIRS,—Dr. Steavenson appears, from his letter in your issue of Dec. 7th, to have misunderstood my paper. He has, I have no doubt unintentionally, misrepresented my deductions drawn from experimental evidence. He states in his letter that "the experiments brought forward by Dr. Parsons to prove that no change takes place between the poles, &c." Now, I have never said that *no change* takes place. I will quote my words as they were printed: "All these experiments demonstrated in a conclusive way that the passage of a constant current does not cause any *decomposition* between the poles, although there must of necessity be an exchange of atoms between the molecules." I actually state that there is a change in the interpolar region, but no decomposition. Dr. Steavenson's views appear to me to be fallacious, and his own experiments help to prove my deductions and to refute his own theories. I will endeavour to make this clear. When a constant current is passed through any given portion of the body, acids are found to appear at the positive pole and bases at the negative pole, and they are found at the poles only, and not in the space between them. Water furnishes the simplest example of this decomposition of molecules, when hydrogen appears at the negative and oxygen at the positive poles. Is this *decomposition* confined to the area in contact with the poles, or does it take place throughout the area between them? It was this very important question, from a practical point of view, that I tried to elucidate by experiment. To put it in a practical form: Supposing a tumour is buried in the liver, and one pole from a battery is placed on the right hypochondrium, while the other is placed in such a position on the back that the current between them passes through the liver. We find acids and bases at their respective poles on the skin resulting from the decomposition of molecules. Are these acids and bases derived from the tissues in contact with the poles only, or do the whole of the deeper parts traversed by the current participate in the decomposition? I devised the following experiment to try to ascertain what happened, using the same diagram. The three cups, A, S, B, were filled with a standard

Digitized by Google

solution of iodide of potash, and connected together by a stout lamp-wick saturated in the solution. The two platinum electrodes from a battery were then brought, one into each of the end glasses, A and B. The experiment arranged in this way presents in one respect a similarity to the application of the current to the body. Because there are only two poles, and the acids and bases appear in their neighbourhood only in the two end glasses, the centre glass, S, contains no pole, and it can therefore be used to represent the deeper parts of the body away from the poles, and called the interpolar region. After passing a constant

current for some time, I found that the iodide of potash in the end glasses, A and B, was decomposed into iodine and potash, while in the centre glass no decomposition had taken place. It still contained as much iodide of potash as before. Dr. Steavenson does not say whether he has tried this experiment in the same way, or whether he obtained a similar result. But he alters the experiment and connects the glasses with copper wires, and of course a different result follows. If copper wires be used to connect the glasses, there are two poles in each glass instead of one pole in each of the end glasses. The centre glass, instead of containing no pole, actually contains two. It therefore ceases to represent the interpolar region. The experiment thus carried out by Dr. Steavenson is utterly useless for elucidating the point under discussion. His third experiment, as well as his second, prove in a remarkable way my contention that "there is no decomposition between the poles, although there must of necessity be an exchange of atoms between the molecules." To take his third experiment as the best example, he places dilute sulphuric acid in the centre glass, S, and a solution of chloride of barium in the two end glasses, A and B. Now what happens after the passage of the current? The dilute sulphuric acid, instead of decomposing, exchanges its atoms of hydrogen for atoms of barium, and forms sulphate of barium, which remains in the centre glass undecomposed. This proves the two very points that I contend for, that there is an exchange of atoms by the molecules, but no decomposition in the interpolar region. My clinical experience, when ether is given, is quite the reverse of Dr. Steavenson's theory that electrical shocks cause inhibition of the heart. I passed 600 milliampères across the pneumogastric in the neck in a case of Dr. Burton's, and the circulation, if anything, improved. By comparing the action of the constant current on cancer with that by the interrupted voltaic current, I find that the former produces a destruction of tissues, both healthy and morbid, close to the poles, while the cells in the interpolar region retain their vitality; that the interrupted voltaic current apparently causes atrophy of the morbid cells from pole to pole in the path of the current, if the details of the application are efficiently carried out.

I am, Sirs, yours faithfully,

Collingham-place, S.W., Dec. 9th, 1889. J. INGLIS PARSONS.

THE MORTON LECTURE ON CANCER.

To the Editors of THE LANCET.

SIRS,—In reference to the letter of Mr. Marshall in your issue of Saturday last, and also to that of Dr. Inglis Parsons of the preceding week, may I be permitted to call attention to a short paper of mine on the intimate nature of Cancer, which I published in THE LANCET of 1863, vol. ii., page 713, in which I expressed views on this point almost identical with those which these two able writers have so recently done, and which views were further commented on by me in 1868.[1] I am sure we have all read Mr. Marshall's closely reasoned lecture with the deepest interest, and also gladly welcome Dr. Parsons' suggestions; and further feel of how little real consequence it is who may have first taken a particular view of the subject so long as it is true, whilst I am quite aware that some other author or authors may have preceded myself in the thoughts I have there expressed. But whilst I feel sure that we all care little except for the true elucidation of this dire disease, yet as a question of precedence has been raised, it seems to be but justice to myself to point to the above paper of mine published so long ago as 1863. I am, Sirs, yours faithfully,

Norwich, Dec. 9th, 1889. PETER EADE, M.D., &c.

[1] THE LANCET, vol. i., page 603.

COMPULSORY VACCINATION.

To the Editors of THE LANCET.

SIRS,—You have now been good enough to honour me with a third paragraph in your journal under the above heading. In the first you were misled into attributing to me what I did not say. In the second you withdrew that error, and promised to comment on what I did say. In the third you do so comment, promising that your readers will be thus enabled "to judge of the accuracy" of my assertions. Your comment on my assertion, that in the Perth Infirmary in 1887 there were eight revaccinated cases of small-pox with two deaths, consists of a counter-assertion by Dr. Graham that of the eight cases information as to the revaccination was wanting in five, and that in two more the revaccination had only immediately preceded the attack; and that the two deaths were taken from these seven cases. I can only reply that this account of events now two years old differs materially from that given at the time by Mr. P. Campbell, one of the directors of the Perth Infirmary. The following extract from a letter of his, dated Perth, Nov. 15th, 1887, now lying before me, was the authority for my statement:—

"As you are desirous of knowing about the patients who had small-pox in the Perth Infirmary, I made inquiries of the house surgeon this morning. Of the eight patients, six recovered and two died; all had been at least twice vaccinated, and some of them three times. The two who died had been twice vaccinated, but the one was far gone with heart disease and the other had a complication of troubles as well as small-pox."

Your readers, whilst judging of my accuracy, will not fail to judge of the discrepancy of these two accounts. Clearly, on Nov. 15th, 1887, the house surgeon had no doubt as to the revaccination of all his eight cases. And the complications then alleged by the house surgeon as explanation of the two deaths are unknown now, or at least unmentioned, by Dr. Graham. I might therefore follow your example, and call on your readers to judge of the accuracy of Dr. Graham. But I prefer to avoid a phrase which might seem to reflect on the truthfulness of a gentleman quite unknown to me. Evidence, indisputable and undisputed, of the failure of revaccination to protect from small-pox lies so ready to my hand that I have no need and no desire to specially defend any particular disputed case. My object in asking the insertion of this letter is simply to defend my own "accuracy," and to show that I did not make the statement in question without good and sound authority.

I am, Sirs, yours obediently,

ALFRED MILNES, M.A., F.S.S.

Goldhurst-terrace, N.W., Dec. 8th, 1889.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Appointment of a Lecturer on Diseases of Children at Liverpool University College.

DR. PETER DAVIDSON has been elected Lecturer on Diseases of Children at the Medical Faculty, University College, Liverpool. He has had considerable practical experience in the department of medicine on which he will lecture, having been for some years past honorary physician to the Infirmary for Children, honorary medical officer to the Bluecoat Hospital, and medical officer to the Industrial Schools, Liverpool.

Cases of Longevity.

Some weeks ago there appeared in THE LANCET notes of extraordinary longevity in a man who resided in

Digitized by Google

Liverpool, and had long passed his hundredth year. Two more instances of extreme old age in local residents have now to be recorded. The first is that of a female who died recently in a Home for the Aged, which she entered on attaining her 100th year, reaching at her death the advanced age of 108. The case appears to be well authenticated, the deceased having been born in 1781. Though a native of Ireland, she had lived in Liverpool many years, and her son, who is still employed here, is seventy-eight years of age. She was seventeen years old at the time of the Irish Rebellion. The second case is that of the Rev. John Jones, or, as he was most generally called, Archdeacon Jones, though he resigned that office some years ago. He was born in London on Oct. 6th, 1791, had completed his ninety-eighth year, and at the time of his death, on the 5th inst., was, it may be assumed, the oldest clergyman in the Church of England. His father was of Welsh descent, and a captain in the army. The deceased took his B.A. degree in January, 1815, in which year (seventy-four years ago) he became deacon, "minister designate," of St. Thomas's, Seaforth, near Liverpool, priest and first incumbent of St. Andrew's, Liverpool. Here he remained thirty-five years, having considerable reputation as an eloquent preacher and earnest worker. It is a curious coincidence that in the same year (1815) which was so eventful to him the watering-place of Waterloo was formed, being so named after the famous battle of that year. It subsequently became a large and important township, and here Mr. Jones came as incumbent of its then only church in 1850. He continued the duties of archdeacon, to which office he was appointed a few years later, till 1886, and was able to take some slight part in the service even more recently. He retained most of his faculties up to within a very few years, and his memory remained unimpaired almost up to the last, till which time he was conscious. As an example of his strength and vigour, it may be mentioned that six years ago he fractured his thigh, but made an excellent recovery, though with a false joint.

The proposed Criminal Appeal Court.

The assizes commenced on the 6th inst., and in his charge to the grand jury Justice Grantham alluded to the wish which had been so frequently expressed for a Court of Criminal Appeal, indicating, without naming, the Maybrick case as the one which had led to its demand. He pointed out that the *modus operandi* in civil and criminal cases was totally dissimilar, that adopted in criminal cases being all along fair and open towards the accused, from the moment of arrest by a police officer until the final determination of the case by the jury; in fact, that the wish appeared to be to get the prisoner off. He contended that the present system worked well, that the Home Secretary possessed powers which a Court of Criminal Appeal would not have, and that the effect of such a court would be to render common juries as careless and indifferent as they are now careful and painstaking.

Paraffin Lamp Fatality.

A woman died at Birkenhead last week, another victim to paraffin lamps. Notwithstanding the many warnings which have been given as to the dangers of such a practice, she attempted to put out a lamp by blowing down its chimney. A loud explosion followed, and the unfortunate woman died within a few days from the injuries received.

Liverpool, Dec. 10th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Assizes.

THE assize recently concluded here was a very heavy one. Amongst the cases tried were two in which members of the profession figured as prosecutors. A discharged attendant at the Prestwich Asylum was charged with violently assaulting Mr. Ley, the medical superintendent, the only grounds for this being that he had been discharged by Mr. Ley for misconduct. The judge characterised it as "a cowardly attack on an unsuspecting man," and sentenced the prisoner to nine months' imprisonment. The second case was illustrative of one of the perils and annoyances that beset the medical practitioner in his daily work. Jane Boston, a young woman, was indicted "for having written and published a false, scandalous, and defamatory libel" upon Mr. T. H. Pinder, surgeon, practising in one of the suburbs of this city. Mr. Pinder is well known in Manchester, as a man of high character and standing, holding honorary appointments at various of our charities. The prisoner had received the greatest kindness at his hands, and not only had he treated her for some time gratuitously, but had actually assisted her pecuniarily when she was in much distress from continued ill health. It was not in the least suggested that any improper relations had existed between them. The prisoner had got some delusion into her head at a time when she was under the influence of morphia, and she had written and circulated most damaging statements about Mr. Pinder. Counsel for the prisoner admitted that there was no real defence to the charge, except the fact that the woman's mental condition was such as to render her scarcely responsible for what she did. His lordship said that the prisoner "had made the gravest imputations on the character of Mr. Pinder. It was now made clear in the sight of all men that these were absolutely false. The language used appeared to be that of a person scarcely in her right senses. A stop must be put to such annoyance. Owing to her condition he would pass the lenient sentence of one month's imprisonment."

Hospital Sunday Fund.

At the annual meeting of the Hospital Saturday and Sunday Funds several interesting statements were made. The two collections this year yielded a total sum of £8210, being nearly £200 more than in the preceding year, this increase being chiefly due to a larger amount received from the Saturday collections, the workshops &c. where weekly contributions are raised steadily increasing in number. The committee complain of the small amount received from the surrounding towns, notwithstanding a large proportion of hospital patients come from these same districts, and they suggest that more stringency should be exercised in admitting and treating patients from towns which do not contribute. An unusual feature in the report was that one hospital (the Barnes House of Recovery) had voluntarily asked the committee not to give it any grant at present, as its income was so large they "did not want the help of this fund." Since Hospital Sunday was first inaugurated a sum of £146,438 has been raised thereby.

Owens College.

Old "Owens men" will hear with regret that Professor Greenwood, the principal, has, owing to declining health, been compelled to resign his office. For more than thirty years he has been one of the chief guiding and directing powers of the College through good report and evil report in its early struggles and during its later magnificently successful career. Dr. Greenwood has proved himself a capable and wise adviser and administrator. His place will not easily be filled. He retires with the respect and grateful good wishes of all old students of the College for a future of well-earned repose from work, the results of which must afford to Dr. Greenwood himself almost unalloyed satisfaction.—On Saturday evening next the College Union give their annual *soirée*, and unusual efforts are being made to render the meeting an enjoyable and interesting one; among other novelties it is rumoured that for the first time on record a dramatic representation is to be given within the College walls.

Health Matters in Salford.

Some stir has lately been made about the manner in which the Salford corporation treat their sewage at the sewage works. Salford, like many other large towns, finds that, after spending large sums of money, the so-called "chemical treatment" of sewage leaves much to be desired. Following the lead of Manchester, an attempt is to be made (not before it is wanted) to deal with some of the insanitary dwellings of the poor which exist in some of the slums of the borough. After much and prolonged delay, steps are now being taken in earnest to proceed with the erection of the new Fever Hospital. The old one in Cross-lane is still very full, owing to the continued prevalence of diphtheria and scarlet fever; the latter disease shows but little sign of abatement either in Manchester or Salford, more than 260 cases having occurred during the past month. The Fever Hospital at Monsall also is quite full, the last return showing nearly 300 patients in the wards, and since June 24th of this year there have been more than 1200 admissions into this hospital alone.

Dec. 11th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Newcastle.

AT the Royal Infirmary a resolution has been carried which can do the institution no good, while its propriety is very questionable. It is "that a monthly statement be placed on the table of the quantity of intoxicating liquor ordered, and by whom." Some time ago exception was taken to the quantity of soda water used, and aerated waters in general were objected to. I suppose some of the governors will not rest satisfied until "Whittle Dene" (as the pipe water is called in this district) is duly tabulated "how much" and "by whom." At a time when the governors are crying aloud for pecuniary support, this "cheeseparing" policy is scarcely to be commended, while I know it is offensive to some of the medical staff. If the patients get to think that anything ordered for their benefit by their medical attendant is given with a bad grace, it is certain to react in a way detrimental to the institution. — The Northumberland and Durham Miners' Permanent Relief Fund is probably one of the largest benefit societies in existence, and seems to be managed with much prudence. It was stated on the opening of their new premises in Newcastle on Saturday last that the membership now was just 100,000. They had distributed to widows and children £234,000, for permanent disablement £116,000, for minor accidents £117,000, and to aged miners for superannuation relief £213,000. Very large figures these, but there are still larger—viz., the total income since the beginning of the Society has been little short of £1,000,000. The management expenses were shown to be below 10 per cent. on the income of the Society—viz., £90,000 per annum.

"Pasteur's Life and Work."

This is the title of the last University free Saturday night lecture, and was delivered last Saturday in Newcastle to a large and appreciative audience by Mr. W. H. Hodgson, B.A. Mr. Hodgson's matter and delivery were excellent, and he did justice to the great French physiologist as a man of unrivalled ability, and one exhibiting the utmost devotion to science.

Newcastle-on-Tyne, Dec. 11th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

EDINBURGH.

Edinburgh University Court.

AT the meeting of the University Court held on Monday the following matters of interest were discussed and arranged. Consideration of the proposed alterations by the Aberdeen University Court on Ordinance No. 16, as to the arrangement of the professional examinations for graduation in medicine at Aberdeen University, was resumed; and the reply of the Aberdeen Court to the observations of the Glasgow and Edinburgh Courts and the remarks of the Glasgow Court and a minute of Senatus relative to the reply was considered. The minute of Senatus was in favour of the proposed alteration. The Court remained of opinion that some of the proposals required further experience at the University of Edinburgh, in which they had been carried out, before it would be prudent to carry them further, and that the appointment of an Executive Universities Commission made it inopportune to proceed with the proposed alterations before Her Majesty in Council under the Act of 1858. The usual arrangements made for the appointment of additional examiners in Natural History and Clinical Surgery at the meeting on Monday, Jan. 20th, 1890, were approved of. The appointment of Dr. John Playfair to be one of the lecturers on the Diseases of Children, in succession to Dr. Underhill, whose term of office had expired, was endorsed. On consideration of a minute of Senatus, the Court approved of the continuance of the salaries of the secretaries and of the deans of faculties for the current session.

Edinburgh Health Lectures.

On Saturday evening Dr. Noel Paton delivered the fifth of the series of lectures to the Health Society on "Vegetarianism and the Use of Vegetables in Diet." He pointed out the manner in which the waste of the body is repaired, and then went pretty fully into the consideration of what kinds of foods were necessary to replace the waste and to produce the necessary energy. A comparison of animal and vegetable food stuffs, with their relative proportions of proteids, fats, and starches, was given; and then Dr. Paton, summing up, said that vegetarianism was possible to those who had a good set of teeth, a sound digestion, plenty of out-door exercise, and a knowledge of dietetics. Hence, vegetable diet was more to be recommended to the outdoor labourer than to the dweller in towns. Pulses were the best forms to use, and these, along with butter, lard, or vegetable oils, formed an excellent diet. The object to be kept in view should be to combine the vegetables so as to give the necessary food ingredients in their proper proportions. In closing, Dr. Paton said that, while he was no champion of exclusively vegetable diets, he could not but feel that, among the poorer classes especially, the use of vegetables in diet was sadly ignored. Money was needlessly squandered on flesh food, from the idea that it was strength-giving, while many of the cheaper vegetable foods were of equal value with the more expensive animal food stuffs.

Edinburgh Medical Missionary Society.

At the annual meeting of this Society, Professor A. R. Simpson presiding, a most interesting account of the work of the past year was presented. Much valuable work has been done at the Livingstone Memorial Training Institution and Dispensary. Patients had been visited at their own homes, midwifery and other cases had been attended, and no fewer than 10,089 patients had been seen. Since 1880 forty-four students had left the institution for the foreign mission fields. Six young men were received as students last year, making in all twenty-eight in connexion with the Society at the present time. Eleven men finish their studies during the year, and will be prepared to go forth as fully qualified medical missionaries. Owing to the growing success of the work there is need of more room and more money, both of which, the managers hope, will soon be forthcoming.

Royal College of Physicians of Edinburgh.

At the annual meeting of the College, held on the 5th inst., the following office-bearers were elected for the ensuing year:—President: Dr. Thomas Grainger Stewart. Vice-President: Dr. Robert Peel Ritchie. Council: Drs. G. W. Balfour, R. Peel Ritchie, D. J. Brakenridge, Batty Tuke, James O. Affleck, John Sibbald. Treasurer: Dr. Peter A. Young. Secretary: Dr. George Alexander Gibson. Librarian: Dr. George W. Balfour. Curator of Museum: Dr. Thomas A. G. Balfour. Curator of Laboratory of Research: Dr. John Batty Tuke. Registrar of Applicants for the Licence: Dr. George A. Gibson. Superintendent of Laboratory: Dr. German Sims Woodhead. Representative of the College in the General Medical Council: Dr. John Batty Tuke.

Edinburgh, Dec. 10th.

GLASGOW.

Election of University Assessors.

Under the Universities (Scotland) Act the General Council of each University, which is understood to represent specially the views and feelings of the graduates, is entitled to send three representatives to the University Court as recently reconstituted. In the case of Edinburgh this has been done without the trouble and expense of a contest; but in Glasgow it is otherwise, six candidates being before the electors. The result of this election will determine to a considerable extent the amount and the kind of reform which may be looked for in the University for a considerable time, as the Court has, at first at any rate, very important duties to perform; the interest taken in the contest therefore is keen, and the voting will be close. Two sets of candidates for the three seats have been proposed. By the organisation known as the University Club the claims of Dr. H. C. Cameron, Sir J. N. Cuthbertson, and Mr. David Hannay are being pressed on the attention of the constituency; while by the University Council Association the candidates favoured are Mr. M'Vary Campbell, Sheriff Guthrie, and Dr. D. C. M'Vail. The Club advocates university reform of a measured and well-considered kind, more especially reform within, and upon the lines of the existing university

Digitized by Google

organisation, and its candidates are pledged, though in a somewhat indefinite way, to support proposals for such changes. On the other hand, the Council Association, while it also advocates reform, does so "with a difference;" its views are more thorough-going, and its proposals more drastic, including such reforms as a fuller occupation of extra-mural teaching by affiliation of colleges and otherwise, the widening of the basis of the Arts curriculum and examination, the exclusion of teachers from any considerable share in the examination of their own students &c., and its candidates are distinctly pledged on these points. The show of hands at the meeting of Council called to elect the three assessors resulted as follows: the numbers were—for Dr. Cameron, 128; Sir J. N. Cuthbertson, 122; Mr. D. Hannay, 120; Sheriff Guthrie, 81; M'V. Campbell, 78; Dr. M'Vail, 66. Of course these figures give only a very rough indication of the probable result of the poll next week, as the meeting was comparatively a small one, while the constituency is large and widely scattered. Probably a majority of voters will refuse to be influenced entirely either by Club or by Association views, and will not vote for the candidates in sets, but will select from among the six those whom they think most worthy of honour. The Club was first in the field, and has in the main strong candidates; if it succeeds in carrying them, the senatorial party will have a powerful, perhaps even a preponderating voice in the decision of the Court. Negotiations, characterised by much astuteness on both sides, for a compromise and the avoidance of a contest, were engaged in between the two nominating bodies, but they came to nothing—fortunately perhaps, as the Council as a whole will now have an opportunity of giving its voice decisively on one side or the other on the reform question. The assessors appointed to the new University Court by the Senate of the University are Sheriff Berry, Professor Leishman, and Professor Stewart.

The Disturbance in Glasgow University.

Sir George Macleod is right in stating, in THE LANCET of last week, that this disturbance was greatly exaggerated and made the most of in the local newspapers. The paragraph which appeared in THE LANCET, however, was carefully prepared; the exact facts, so far as known to the writer, were stated, and sensational reports excluded. Your correspondent regrets that he should have fallen into any error in describing the treatment which Sir George Macleod experienced. The matter has been under the consideration of the Students' Representative Council, which has protested against the exclusion of students from graduation ceremonies, has expressed regret for the recent outbreak of violence, has offered to aid the Senate in future in maintaining order, and made the claim that complaints regarding disturbances among the students should be sent to it. The Senate sends to this a dignified and not unkind reply, acknowledging the above resolutions, expressing satisfaction on receiving the reports of the Council, and accepting cordially the proffered aid in keeping order on future occasions. The differences between students and Senate may now be said to be happily settled.

Glasgow, Dec. 12th.

ABERDEEN.

The University.

At a meeting of the Senatus held on Saturday, the 7th inst., Professors Hay, Pirie, and Stephenson were elected assessors to the University Court in addition to Professor Milligan, the present representative. An examination for the Public Health Diploma was held recently, when five candidates were successful. At the examination in July last there were eleven or thirteen candidates, but only three were successful in obtaining the diploma.

Should there be a Pay Hospital in Aberdeen?

In the *Free Press* of the 5th inst. there is a short article by Dr. Robert John Garden on the question of a pay hospital for Aberdeen. He divides those for whom a pay hospital is required into two classes—viz, first, those of limited means who could afford to pay but a moderate sum for their board and treatment, "poor paying patients," such as small farmers, clerks, shopmen, students, &c.; and secondly, those who have ample means, but who from various circumstances find it inconvenient to be treated at their places of residence; these could afford to pay well for hospital treatment. Dr. Garden shows that it is impossible to have pay wards in the new hospital being built, but has no hesitation in answering in the affirmative the question with which he heads his article, and he feels convinced that if a pay hospital were started on a broad footing, fair to all possible interests, it would not only prove a success, but be a boon both to the city of Aberdeen and to the north of Scotland.

Aberdeen, Dec. 10th.

DUBLIN.

(FROM OUR OWN CORRESPONDENT.)

Expenses of Medical Witnesses.

AT the Munster Assizes this week an application was made to Mr. Justice Murphy with reference to the expenses of medical men attending as witnesses—namely, that they should be allowed an amount beyond that granted by the Treasury, which was totally inadequate, on account of the long distances witnesses had to come, and the high prices charged for accommodation at Nenagh. Mr. Justice Murphy said he would be glad to make the order asked for in cases where it was manifest that medical gentlemen had been put to great inconvenience, but he could not interfere with the decision which the judges had arrived at. If, however, a representation were made to the Treasury, something satisfactory might be done. I understand that this matter was brought under the notice of the judges about a year since, when they decided that the rules laid down by the Treasury should be adhered to.

Death of Mr. Jameson Dwyer of Cork.

This gentleman, who held the responsible post of resident medical superintendent of the Cork District Lunatic Asylum, died last week. He had been ailing for the past two years from an affection of the stomach which ultimately proved to be of a malignant nature. Mr. Dwyer immediately after being qualified applied himself exclusively to the practice of lunacy, and was some time afterwards appointed assistant medical superintendent at the Castlebar, and afterwards at the Mullingar Asylums. He left the latter institution to take charge of the Cork Asylum when Dr. Eames died in 1886, having been appointed by Lord Aberdeen, who was then Lord-Lieutenant. Mr. Dwyer possessed considerable administrative abilities, and effected many important improvements in the Cork Asylum.

Notification of Infectious Diseases.

The Local Government Board have issued a notice to the several urban and rural sanitary authorities in Ireland to whose districts the Infectious Disease (Notification) Act, 1889, may extend. The Act provides that where an inmate of any building used for human habitation within a district to which the Act extends is suffering from an infectious disease to which the Act applies, then, if not a hospital, every medical practitioner in attendance shall send to the medical officer of health for the district a certificate stating the patient's name, age, the locality, and the nature of the disease, &c. In the case of a ship, tent, van, or shed, the name and description and the place situated must be given in the certificate prescribed for the purpose. The penalty for not forwarding the certificate is forty shillings. The Act applies to the following diseases—viz., small-pox, cholera, diphtheria, croup, erysipelas, scarlatina, and typhus, typhoid, continued, and relapsing fevers, also to puerperal fever, and any other infectious disease to which the Act has been applied by the sanitary authority.

The Right Hon. Viscount Monck has appointed Mr. Meldon, President of the College of Surgeons, to be a Deputy Lieutenant of the City of Dublin.

The many friends of Dr. Neville, who from delicate health was obliged to leave Dublin some time since, will be gratified to learn that he has now resumed practice.

Dublin, Dec. 10th.

PROPOSED INFECTIOUS DISEASES HOSPITAL AT TODMORDEN.—The late Mr. S. Fielden, of Centre Vale, Todmorden, had taken steps towards providing a hospital for infectious diseases at Sourhall for the whole of the Todmorden Union and the borough of Bacup. The plans are already in a forward condition.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Pasteur Institute.

THE Council of Administration of this institution met recently for the purpose of hearing the report of M. Pasteur on the work accomplished by the institution during the past year. The department for the treatment of the disease for which the institution was mainly established—viz., hydrophobia,—and which is under the joint direction of MM. Grancher, Chantemesse, and Charrin, has treated during the period embraced between Nov. 1st, 1888, and Nov. 1st, 1889, altogether 1830 persons, of whom eleven succumbed notwithstanding treatment. This gives a mortality of 0·6 per cent. Of the eleven, however, four died during the treatment, and these being subtracted, as M. Pasteur thinks they should be, from the statistics, the mortality is reduced to 0·3 per cent., a better result even than that obtained last year. M. Pasteur observes that the mortality amongst the persons certified by veterinary surgeons to have been bitten by animals proved to be rabid amounts to 16 per cent., while of those actually bitten by animals whose hydrophobic condition was shown by subsequent inoculation experiments, and this, M. Pasteur adds, is satisfactory evidence that the certificates as to the condition of the animals are given after careful inquiry and diagnosis only. As of course your readers are aware, the treatment and cure of rabies are not the only objects pursued by the institution. The study of virulent and contagious maladies and the application to hygiene and the biological sciences of the discoveries made in regard to the microbe, are not less earnestly studied. During the past year to wit, several important contributions to these studies have been made by the staff, and by observers, such as MM. Duclaux, Roux, Chamberland and Metchnikoff. On a review of the work done, one sees the scientific activity prevailing in this celebrated institution—an institution which reflects such honour on French science and its illustrious founder, and of which every Frenchman may well be and is justly proud.

An Epidemic at the Louvre Warehouses.

A good deal of sensation and capital are being made by a certain portion of the daily press out of an epidemic the nature of which is not yet very clearly defined, but which appears to have spread with somewhat remarkable rapidity amongst the numerous staff of employés of the enormous—chiefly soft goods—warehouses situated opposite the Louvre Picture Gallery, and known as Les Grands Magasins du Louvre. The alarm, however, raised by the daily papers does not appear to be at all warranted so far, for although about 450 of the workers in the warehouse are reported to be ill, as a fact, there have been no fatal cases mentioned. The exact nature of the epidemic is, as I said, not yet made clearly out, but as far as I can learn it is not of a virulent character, and amongst the inmates there is no doubt. The symptoms as so far announced, would seem to lead to the conclusion that one had to do with an outbreak of epidemic influenza, but whether this will be confirmed by subsequent investigation, remains to be seen. An official inquiry was ordered by the Minister of the Interior, who appointed MM. Brouardel and Proust to carry it out. They visited the Louvre Warehouse to-day, and reported that the outbreak is one of mild influenza, for the maximum duration never appeared to exceed four days. The numbers absent from duty had increased daily from 120 (out of 3000 employés) on Nov. 26th to 670 on Dec. 10th. They could not arrive at a conclusion as to the origin of the epidemic, which they state is not of a kind to excite alarm. It must be remembered, in reading the popular accounts of this epidemic, that side by side with the epidemic itself there is another, which has spread with greater rapidity—viz., the epidemic of emotional alarm.

Paris, Dec. 10th.

PROPOSED SEWERAGE BOARD, CHERTSEY.—The necessary parliamentary notice has been published in reference to this new board. The scheme of sewerage proposed is on an extensive scale, and it is stated that the opinion has been expressed by those who have examined the plans prepared that it will be favourably received.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Influenza Epidemic.

LAST week some cases of influenza occurred at the General Hospital here. Physicians, nurses, and patients who were already under treatment in the hospital for a longer or shorter period on account of other maladies, were affected by this disease, which, although commencing with high fever, was not accompanied by any serious complications. The number of cases of influenza at the hospital reached nearly fifty, and some excitement ensued as it became difficult to keep the medical service at the hospital in order. According to communications made to me by some of the leading physicians practising in the town, single cases showing the character of influenza were also observed in private practice. As to the etiology of the disease, some physicians here have commenced to make bacteriological examinations, and within a short time the discovery of a bacillus or micrococcus to which the outbreak of the disease is due will, it is expected, be reported. The view that the disease is connected with electrical disturbance, as well as the difference between the temperature of the overheated rooms in the houses and the air outside, and the presence of sulphurous acid in the air, must be taken into consideration as etiological factors. Reports from Cracow and Lemberg (Galicia) on the outbreak of an influenza epidemic in those towns, especially among the soldiers, were received yesterday. It must be also noted that till now the epidemic has not made its appearance in small country villages, not even in Russia. The view of Professor Zdekauer of St. Petersburg, who is inclined to regard the Petersburg epidemic as a precursor to the spread of cholera, is contested by the Vienna authorities on epidemiology.

Actinomycosis in Vienna.

According to a communication made by Professor Albert no less than thirty-five cases of actinomycosis have been treated at his clinic since the year 1883; whilst this winter session, which commenced Oct. 1st, eight cases have already been under his treatment.

A New Micro-organism in Milk.

Dr. Adametz, assistant at the High School of Agriculture, has discovered a new micro-organism by whose action the milk becomes viscid; it is a micrococcus embedded in a mucilaginous substance.

Vienna, Dec. 8th.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an ordinary meeting of the Council of the above College, held on Thursday, the 12th inst., the minutes of the last meeting were read and confirmed.

A report from the General Purposes Committee on the fittings for the extension of the Examination Hall, and on the uses of the extension of that hall, was read and approved, subject to the approval of the Royal College of Physicians.

It was agreed that, as recommended by the Nomination Committee, the annual election of Examiners in Elementary Anatomy, Elementary Physiology, Anatomy, Physiology, and Midwifery for the diplomas of Fellow and Member respectively, do in future take place at the ordinary meeting of the Council in June on a report from this Committee to be presented at that meeting, and that the examiners in such subjects be appointed for *six* months, and be subject to re-election in June next.

Messrs. Langton and Pick were re-elected members of the Court of Examiners in Surgery, and Mr. Edmund Owen was elected to the vacancy caused by the resignation of Mr. Hulke. Mr. Langton was reappointed a member of the Court of Examiners in Dental Surgery, and Mr. Pick elected to the vacancy caused by the resignation of Mr. Hulke.

The best thanks of the Council were given to Mr. Marshall for his delivery of the Morton Lecture, and to Mr. Bryant for his delivery of the Bradshawe Lecture, and they were requested to publish the same.

The following gentlemen were elected examiners for the

Digitized by Google

ensuing six months, namely:—*First Examination*—Elementary Anatomy: Messrs. C. A. Ballance, A. Hensman, W. Arbuthnot Lane, C. Lockwood, and C. Stonham. Elementary Physiology: J. R. Bradford and W. G. Spencer. *Second Examination* — Anatomy: Messrs. W. Anderson, J. N. C. Davies Colley, F. H. Marsh, and G. D. Thane. Physiology: C. H. Golding Bird, V. D. Harris, and B. T. Lowne. *Third Examination*—Midwifery: W. Duncan, M.D., W. S. A. Griffith, M.B., P. Horrocks, M.D., and J. B. Potter, M.D. *First Examination for the Fellowship*—Anatomy: W. H. Bennett, W. B. Clarke, A. P. Gould, G. H. Makins, and F. Treves. Physiology: C. H. Golding-Bird, B. T. Lowne, D'Arcy Power, and G. F. Yeo.

A letter was read from Mr. John Marshall, President of the General Medical Council, reporting, as representative of the College, the proceeding of that Council at their late Session, and thanks were voted to Mr. Marshall for his efficient services.

A letter of Nov. 26th, 1889, was read from Mr. Arthur Milman, Registrar, forwarding, by direction of the Senate of the University of London, copies of the scheme approved by the Senate for the reconstitution of that University on the general lines indicated by the report of the University for London Commission, inquiring if this College will concur in the proposal that its President should be an *ex officio* member of Senate, and inviting any observations and suggestions upon the details of the scheme which this College may think fit to make.

A committee of delegates of the College was appointed to consider the same and report to the Council. The members of this committee are the President and Vice-Presidents, Mr. Savory, Mr. Power, Mr. Hulke, Sir W. Mac Cormac, Mr. Sibley, and Mr. Pick. A letter was also read from Dr. R. Quain, Chairman of the Pharmacopœia Committee of the General Medical Council, stating that it is the intention of the General Medical Council to publish an addendum to the British Pharmacopœia, 1885, and requesting the Council to assist the committee appointed for the purpose by forwarding to them a list of such new remedies as they may think it desirable to introduce into the addendum. This was referred to a committee consisting of Messrs. Lund, Hill, Sibley, and Howse.

A letter of the 28th ult. from Mr. J. Sebag Montefiore, was read, soliciting a contribution from the College to the funds of the Royal Sea-bathing Hospital at Margate. The Council was unable to accede to this request, as there are no funds at the disposal of the Council for that purpose.

Obituary.

WILLIAM EYRE BLENNERHASSETT ATTHILL.

THIS gentleman, the eldest son of the late Mr. Porter Atthill, formerly Attorney-General and later Chief Justice of St. Lucia, a nephew of Dr. Lombe Atthill, who died in St. Mary's Hospital on Nov. 21st in his forty-first year, was formerly a student at St. George's Hospital. Notwithstanding his good family connexions, he was early obliged to depend on his own efforts and resources, and so it was that in after-life he was one of those men who seem able to turn their hands with success to anything. When the Franco-German war broke out he was amongst the first to offer his services, and was the life and soul of the party which went out with Dr. Mayo, and which founded and was for many months connected with the Alice Hospital at Darmstadt. There it was that the writer of this notice first met him and formed a friendship with him which he highly valued. A series of papers which Mr. Atthill wrote at this time in the *Medical Times and Gazette*, entitled "The Autumn Tour of a Dresser," attracted some attention. Back from the war, he qualified himself for the M.R.C.S. and L.R.C.P. Lond. as soon as he could, and maintained himself both before and afterwards by acting as *locum tenens* or assistant. He thus gained so wide a familiarity with the routine of private practice that he was well prepared when, in 1873, soon after his marriage, a practice was offered him at Waterbeck, near Ecclefechan, in Dumfriesshire. There he worked hard for two years in a wild, cheerless, mountainous district, living in a two-roomed cottage without comforts of any kind. But his natural energy and resources stood him in such good stead that when he moved to Faversham he had some means in hand from the practice which he had made at Waterbeck. He was at Faversham for eleven years, and since that time he had had a large city practice which entailed an enormous amount of very trying work. Throughout it, it was painfully manifest to his friends that his health was failing, and that he was looking prematurely aged. The seeds of the disease to which he succumbed had indeed long been sown. From early boyhood he had been subject to hæmaturia, which in recent years had become more frequent, and was complicated by occasional retention. Then followed the inevitable cystitis with all its distressing consequences, and the loss of sleep told heavily upon him. From time to time during the past few years he had consulted Mr. Buckston Browne, who on Jan. 15th, 1888, washed out his bladder and detached a portion of so-called papilloma, confirming thereby the suspicion which had been entertained as to the cause of his symptoms. Suprapubic cystotomy was discussed but not then urged, and as this examination was followed by a cessation of the bleeding, and Mr. Atthill could not leave his work, it was for the time abandoned. The spring and summer of this year, however, brought a return in much worse degree of all his former symptoms, and it became urgently necessary on July 20th to do something for his relief, for retention was absolute, the bleeding was profuse, and he was suffering great pain. A large portion of growth was removed on that day by Mr. Buckston Browne from the trigone region of the bladder, but a hardness and thickening which were felt between the fingers in the rectum and the bladder revealed the real nature of the malady and the impossibility of getting the tumour completely away. The relief which followed this operation did not last long, and when the writer saw him in October after the holidays, he found him in such a pitiable state that he at once gave him a bed in St. Mary's, so that he might be where help was always at hand; and there until his death the house-surgeon, Mr. G. C. Davis, attended to him with the utmost devotion and self-denial. The epithelioma had now appeared at the suprapubic wound, and increased with such rapidity that the whole cavity of the bladder was soon blocked up. His sufferings were agonising, and were only partially relieved by frequent injections of morphine, but he bore them all with the greatest bravery, and no word of complaint was ever heard to pass his lips. Thus ended a life of much usefulness, which had been encompassed by many hardships. With better surroundings and opportunities, the deceased might have made a greater mark in the world, for he had exceptional abilities and was a shrewd sensible man. His life was one long struggle, made more difficult by the disease which he carried with him. That he had no faults it would be wrong to say; he himself would have been the last to wish that that should be said of him; but he was a thoroughly good fellow, an honourable and high-minded man, and he had qualities which very much endeared him to many besides the widow and children whom he has left.

ROBERT IRVINE,

DEPUTY INSPECTOR-GENERAL R.N. (RETIRED).

DEPUTY INSPECTOR-GENERAL IRVINE died at his residence, St. Margaret's, Twickenham, on Nov. 3rd, aged sixty-five, after an illness of a year and a half. The deceased officer had seen much and distinguished service during the thirty-two years he held Her Majesty's commission. His first appointment, in 1848, was to H.M. brig *Pilot*, on the China station. In 1852 he was appointed to the *Cumberland* (West India squadron), being afterwards present in the same ship at the bombardment of Bomarsund, when he formed one of the first landing party (Baltic medal). During the Crimean war he was attached to Therapia Hospital (Crimean medal and clasp, and Turkish medal). After the conclusion of peace he served in H.M.S. *Esk* on the China station, being present at the capture of Canton (Chinese medal, Canton clasp). His last appointment was to the *Castor* drill-ship of Naval Reserves, North Shields, from which he finally retired in August, 1880. Of a handsome and commanding appearance, coupled with a genial, kindly, and amiable disposition, he was universally liked, and it can be truthfully stated that he never made an enemy, either in or out of the service, and, but for his innate modesty, which prevented him from pressing his claims, he would no doubt have been more officially honoured.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the necessary examinations, were at a meeting of the Council on the 12th inst. admitted Fellows of the College:—

Perry, Francis F., L.R.C.P.Lond., Brookdale, Teddington; diploma dated Aug. 1st, 1876.
Morton, C. A., L.R.C.P.Lond., Zetland-road, Bristol; Nov. 17th, 1881.
Mortimer, J. D. E., L.S.A., Warwick-st., Earl's-court-rd.; Jan. 20th, 1882.
Swain, Jas., M.B.Lond, Royal Infirmary, Bristol; Nov. 14th, 1883.
Crowle, T. H. Rickard, Campden-hill-road; Jan. 24th, 1884.
Murray, R. W., L.R.C.P.Lond., Huskisson-st., L'pool; Ap. 26th, 1884.
M'Lachlan, John, M.B.Edin., Lothian-st., Edin.; July 24th, 1885.
Larkin, Fred. Chas., L.S.A., Bedford-st., Liverpool; Oct. 23rd, 1885.
Jones, A. M., M.B.Dur., Wellow Vicarage, Romsey; Oct. 30th, 1885.
Permewan, Wm., M.D.Lond., Vauxhall-rd., L'pool; July 22nd, 1886.
Pennell, G. H., L.R.C.P.Lond., Heavitree-pk., Exeter; Aug. 2nd, 1888.
Galloway, Jas., M.B.Aber., New-street, E. (Not a Member.)

Two candidates who have not yet attained the legal age (twenty-five years) will receive their diplomas at future meetings of the Council. Twenty-four candidates were referred.

The following gentleman having passed the necessary examination at a previous meeting of the Court of Examiners, and having attained the legal age (twenty-five years) was also admitted a Fellow of the College:—

Ashworth, Percy, L.R.C.P.Lond., Higher Crumpsall, Manchester; diploma dated Aug. 4th, 1887.

The following gentleman, having passed the necessary examination, was at the same meeting of the Council admitted a Member of the College:—

Gilpin, Frank, L.S.A., Charlton House, Pershore, near Worcester.

UNIVERSITY OF OXFORD.—At a congregation held on Dec. 5th the degree of M.D. was conferred on

Dan Astley Gresswell, Christ Church.

UNIVERSITY OF CAMBRIDGE.—At a congregation, held on Dec. 5th, the following degrees were conferred:—

Doctors of Medicine.—George Edward Anson, Trinity; Josias Ernest Viney, Downing.
Bachelor of Medicine.—Arthur Edward Kelsey, Trinity.
Bachelors of Surgery.—George Edward Anson, Arthur Edward Kelsey, Trinity.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE. At a Convocation held on Tuesday, Dec. 10th, the following were recommended for the degree of Doctor in Medicine for Practitioners of Fifteen Years' standing:—

Peter Gordon Bell, L.R.C.S., L.R.C.P. Edin.; Wm. Henry Causton, M.R.C.S., L.S.A.; Geo. William Joseph, M.R.C.S., L.S.A.; George Middlemiss, L.R.C.P. Edin., L.F.P.S. Glas.; Wm. Royston Pike, M.R.C.S., L.S.A.; George Grayson Stopford Taylor, M.R.C.S., L.K.Q.C.P. Irel.; Wesley Hayes Thompson, L.R.C.P., L.R.C.S. Ed.; Eugene John Tulk-Hart, M.R.C.S., L.S.A.

The following were recommended for the degree of M.D.:—

Howard Albert Bredin, M.B., M.R.C.S., L.S.A.; Andrew Seymour Brewis, M.B., B.S., M.R.C.S., L.S.A.; George Gautby, M.B., B.S.; Evan Lewis Hickey, M.B., M.R.C.S., L.S.A.; Thos. Edward Honey, M.B., M.R.C.S., L.R.C.P. Lond.; Samuel Lodge, M.B., B.S.; John Edward Nihill, M.B., M.R.C.S., L.R.C.P. Lond.; John Edward Panton, M.B., M.R.C.S.; Leonard Raby, M.B., M.R.C.S., L.S.A.; Alfred Ernest Richardson, M.B., M.R.C.S.; Leonard Wilde, M.B., M.R.C.S., L.R.C.P., L.S.A.

The following were recommended for the degree of Bachelor in Medicine (M.B.):—

Second Class Honours.—Thomas Wykes Gibbard, M.R.C.S., L.S.A., King's College Hospital, London; Raymond Henry Shaw and James Arnott, College of Medicine, Newcastle-on-Tyne.
Pass List.—Andrew Paige Arnold, College of Medicine, Newcastle-on-Tyne; Wm. John Burleigh-Robinson, London Hospital; Burdon Cox, College of Medicine, Newcastle-on-Tyne; George Blackford Silver Darter, St. Thomas's Hospital; Ebenezer William Diver, University College Hospital; Wm. Alfred Hatton, London Hospital; Robert Guthrie Poole Lansdown, Guy's Hospital; Albert Edward Martin, London Hospital; Wm. Edwin Peacock, College of Medicine, Newcastle-on-Tyne; Chas. Wm. Edward Toller, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; Avery Clough Waters, M.R.C.S., L.S.A., and Robert Jas. Williams, London Hospital.

The following were recommended for the degree of Bachelor in Surgery (B.S.):—

Andrew Paige Arnold and James Arnott, College of Medicine, Newcastle-on-Tyne; George Blackford Silver Darter, St. Thomas's Hospital; Norman Faichnie, M.B., University College Hospital; Chas. Maurice Hardy, M.B., College of Medicine, Newcastle-on-Tyne; Robert Guthrie Poole Lansdown, Guy's Hospital; William Edwin Peacock and Raymond Henry Shaw, College of Medicine, Newcastle-on-Tyne; Avery Clough Waters, M.R.C.S., L.S.A., London Hospital; Thomas Watts, M.B., Owens College, Manchester.

UNIVERSITY OF EDINBURGH.—The following gentlemen have received the degrees of M.B. and C.M.:—

Beilby, J. H., Edinburgh.
Coles, A. C., Bournemouth.
Crawford, W. T., M.A., Worksop.
Crossley, F. E., Harle Syke, near Burnley.
Davies, Rhys, Llanwrtyd Wells, Breconshire.
Dyer, E. E., Bath.
Edwards, A. S., Queenstown, Co. Cork.
Fitzgerald, Jas., Edinburgh.
Forsyth, Ebenezer, Edinburgh.
Frere, A. H., Wickham Market.
Gillespie, S. A. D., Castle Douglas.
Glaeser, E. B., Worcester, South Africa.
Hallen, A. E. H. C., Alloa, N.B.
Hallen, A. H., Stratfd.-on-Avon.
Harvey, James, Edinburgh.
Hewat, M. L., Cape Town, Cape Colony.
Howatson, C. W., Portobello.
Jameson, Hugh, Edinburgh.
Lanyon, G. E., Falmouth.
Lockhart, F. A. L., St. John, N. Brunswick.
Lyle, F. W., Edinburgh.
MacBean, D. F., Islay.
Macdonald, A. H. W., M.A., Edinburgh.
Mackay, Henry, Crouch End, London, N.
Macknight, C. C., Edinburgh.
McNidder, Jas., Crail, Fife.
Mill, G. S., Arbroath.
Murray, C. D., Kirbymoorside.
Munn, J. Gordon, Edinburgh.
Paterson, Walter, Edinburgh.
Penfold, E. A., Pembroke Dock.
Pike, Stewart, Edinburgh.
Platt, A. F. R., Henry VIII. Gate, Windsor.
Poole, T. D., Poulton-le-Fylde.
Robertson, J. H., Edinburgh.
Sakir, H. C. N., Mauritius.
Silver, L. M., Edinburgh.
Spencer, Jas., Burntisland.
Stansfield, T. E. K., Todmorden.
Sylva, J. F. de, Edinburgh.
Taylor, J. A., Edinburgh.
Taylor, Mowbray, Earl's Court-road, London.
Thyne, George, Edinburgh.
Underhill, T. H., West Bromwich.
Wilcox, A. W., Stockton-on-Tees.

THE VACCINATION COMMISSION.—The Royal Commission on the Vaccination Acts resumed its sittings on Wednesday, Lord Herschell presiding. Dr. Creighton was under examination throughout the day.

WIGAN INFIRMARY.—Mr. James Henry Johnson, of the Abram Coal Company, has generously offered to build a children's wing to this infirmary, at a cost of £2000. The offer has been accepted.

MEDICAL MAGISTRATE.—Matthew James Turnbull, M.D., F.R.C.S. Edin., of Tweed View, Coldstream, Berwickshire, has been put upon the Commission of the Peace for that county.

EQUINE LARYNGOSCOPY.—Professor Polansky and Dr. Schindelka, of the Vienna Veterinary School, have constructed a laryngoscope for horses, by means of which active treatment in cases of glanders can be carried out.

THE PUBLIC LIBRARY AT WANDSWORTH.—Dr. Longstaff, who gave a reading-room at a cost of £2000 to the Wandsworth Public Library, has now offered to subscribe £2000 towards the debt remaining upon the library buildings, provided a similar sum be raised by the public before the end of March.

RABIES.—The number of dogs in England officially reported during the week ending Nov. 23rd as affected with rabies was four against eight in the previous week. Of these three were killed and one died. The distribution was as follows;—Kent, London, Surrey, York (West Riding), one each. The number of dogs affected during the week ending Nov. 30th was three, all of which were killed. Of these two belonged to Lancaster and one to London.

ANOTHER DEATH BY ELECTRICITY.—Another workman is reported to have been killed at New York whilst examining overhead lighting wires. An unprotected wire came in contact with the unfortunate man's body, and he was instantly killed. His dead body hung suspended from the wires for some time in the sight of a crowd of people. The victim's forearm and neck were literally roasted, and a portion of his clothing was burned.

A ST. JOHN AMBULANCE ASSOCIATION FOR PARIS. At a meeting held last Sunday at 32, Avenue des Champs Elysées, the residence of Dr. Douglas Hogg, for the purpose of forming a centre for Paris in connexion with the St. John Ambulance Association, an influential local committee was formed, with the Earl of Lytton as president, Dr. Douglas Hogg chairman, and Dr. Barnard hon. secretary. The interest displayed in the classes held by Dr. Barnard this year for the first time in Paris augurs well for the success of this very useful movement, and it is confidently expected that all the English members of the medical profession practising in Paris will shortly be enrolled on the medical staff of the centre. A special feature of the scheme will be the formation of an ambulance corps, the services of which will be available in the event of an outbreak of war.

A SANITARY ASSOCIATION AT CHICHESTER.—At a well-attended public meeting held in St. Martin's Hall last week, it was unanimously resolved to form a Sanitary Association for the purpose of spreading a knowledge of sanitation, and to take from time to time such steps as may seem necessary to promote the sanitary welfare of the city. The chairman, vice-presidents, and honorary secretaries were elected, and a committee of fourteen ratepayers chosen.

LITERARY INTELLIGENCE.—The Chilian Government, having resolved to undertake waterworks on a large scale, have commissioned Señores A. E. Salazar and Carlos Newman, of the Laboratory of the Naval School at Valparaiso, to investigate the water systems of Europe. Their report, together with a chapter on the bacteria of water, contributed by Dr. Rafael Blanchard, Secretary of the Zoological Society of France, is about to be issued by Messrs. Burns & Oates.—Professor Crookshank has presented a copy of his work on the "History and Pathology of Vaccination" to each of the Royal Commissioners.

SANITARY ASSURANCE ASSOCIATION, LONDON.—The President, Sir Joseph Fayrer, occupied the chair at the ordinary meeting of the Council held on Monday last. Arrangements were made for a series of lectures during January and February next, at the College of State Medicine, Great Russell-street. The series will include the following: Mr. H. Rutherford, on "House Sanitation from a Householder's Point of View;" Professor T. Rogers Smith, on "Household Warming and Ventilation;" and Mr. Mark H. Judge, on "The Sanitary Registration of Buildings Bill." Both men and women are invited to these lectures. Particulars can be had on application to the secretary, at the offices, 5, Argyll-place, W.

BEQUESTS AND DONATIONS TO HOSPITALS.—The Treasurer of the Royal Infirmary of Liverpool has received a donation of £500 from the late Mr. T. D. Hornby, given in accordance with his wishes by his executors.—The late Mr. C. Allcock, of Clapham Park, bequeathed by his will £1000 to the Birmingham General Hospital on the death of his wife.—The Duke of Westminster has given £500 to the Chester Infirmary, being part of the proceeds of the shilling tickets of admission sold during the past year for inspecting Eaton Hall.—Sir Benjamin Samuel Phillips, late of Grosvenor-street, London, left by his will £100 each to the London Hospital, the Royal Hospital for Incurables, Sussex County Hospital, the Farringdon Dispensary, and the Metropolitan Hospital.

ATROPINE IN PARALYSIS AGITANS.

J. O'B.—According to Moretti of Rome atropine has succeeded in paralysis agitans when every other therapeutic agent has failed. In a memoir lately read before the Lancisi Society, Dr. Moretti, among other cases, cited that of the distinguished painter, Vertunni, who for years had to abandon his profession owing to the advances of the disease, which, after paralysing both legs and arms, threatened him with asphyxia, but who by the exhibition of atropine regained all his physical powers, and was able to produce pictures in his best manner.

C. R. A.—The disease is undoubtedly cysticercus cellulosæ. The carcase is not unfit for food; and even if the flesh contain the parasite, thorough cooking would surely destroy it.

THE letter of *Mr. Wilkes* (Salisbury) is unavoidably held over until next week, when it will receive attention.

J. G.—The best-known work is that by Dr. Maclachlan (1863), but it is hardly suitable for a lay reader.

M.D.—1. No.—2. The person calling in the medical attendant is liable for the fee.

UNQUALIFIED ASSISTANTS.

To the Editors of THE LANCET.

SIRS,—In a letter published in THE LANCET of Nov. 16th from a correspondent signing himself "An Apprentice of 1846," reference is made to a state of things which demands attention from the "powers that be" at least as much as does the question of the extension of the medical curriculum to five years. This is the excessively free employment of unqualified men as assistants, in- and out-door. Desirable as it undoubtedly is, to quote the words recently used by the President of the Royal College of Surgeons, to "protect the profession against the entrance of imperfectly educated men," it is surely at least equally desirable to afford to those who have at some cost succeeded in entering the profession some protection against excessive and lowering competition from men who have not proved themselves equal to the task. That this grievance is a real and urgent one must be evident to anyone who has had the opportunity of seeing anything of provincial practice. As prominently illustrating this there occurs to me just now the case of a leading practitioner in one of our country towns, of whose large and lucrative practice a very considerable part is worked by a middle-aged man, who is no more legally qualified to practise medicine than the coachman who drives his employer's carriage. The law does not allow to the chemist the free use of unqualified assistants. Why should the medical man claim such a right, to the public harm and his own pecuniary advantage? It seems to me that as the difficulty of entering the profession is increased, so should the difficulty of unqualified practice, whether under cover of assistantship or otherwise, be made to increase.

I am, Sirs, faithfully yours,

Nov. 19th, 1889. A YOUNG G.P.

"A MUNCHAUSEN TALE OF A CANNON BALL."

A GUERNSEY correspondent, referring to the strange inscription above the reading-desk in St. Sampson's Church, a description of which appeared in THE LANCET of Nov. 23rd, writes as follows:—"I may mention that there is a local tradition at St. Sampson's that the way in which the presence of this cannon ball was discovered was this: The soldiers who were carrying the unfortunate young lieutenant off the field on a litter noticed that one side of him was very much heavier than the other. This led to questionings and surmises, ending in further surgical investigation, and then the mass of metal was found. I, of course, merely give this tradition for what it is worth; but I have heard it narrated by old inhabitants of St. Sampson's parish, who thoroughly believed the circumstantial correctness of the whole affair."

Mr. R. H. S. Carpenter.—The letter of our correspondent is too long for insertion, but will have attention.

Mr. R. D. Pedley's paper will appear shortly.

THE INDIAN MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—In a late issue you drew attention to a new ruling, which requires that a medical officer in civil employ must accept promotion when it comes to his turn, the alternative being compulsory retirement. There are other details in this connexion about which Indian medical officers will be anxious to have early information. How, I would ask, does Government, under these circumstances, propose to deal with those officers to whom it has in its discretion refused promotion? Logically, it would seem that these latter should be treated similarly to those who decline promotion, and *vice versâ*. It may, of course, be argued that a man may be fit for executive, but not for administrative, work. This, I admit, may sometimes be the case; but is the officer who has been deemed efficient in all things to be placed at a disadvantage to his brother of a lesser degree of estimated suitability for promotion, each holding, let it be assumed, a lucrative civil appointment? If so, it would manifestly be to the interest of a thoroughly efficient medical officer, when favourably situated, to disqualify for promotion by conveying the impression that he was deficient in administrative capacity. At present an officer to whom promotion has been refused is still permitted to continue in his appointment. Unless, therefore, some provision is made to meet such cases, a grave injustice will be inflicted upon some of those who are officially deemed the most efficient, and the position I have indicated will be forced upon the service, though I do not believe there is a member of that distinguished body who would descend to adopt the alternative mentioned. Still, it will manifestly be impossible for Government to allow matters to remain in their present anomalous position. For instance, three of the most lucrative civil appointments in one of the Indian Presidencies are at present held—the first by an officer who has several times declined promotion, and whose enjoyment of his position has been augmented by an extension of four years beyond the retirement age of fifty-five; the second by an officer of reputation, but to whom promotion has been persistently refused; and the third by a distinguished colleague, who is close upon, but probably does not desire, his promotion. The first is to be congratulated upon having attained his wishes; the second is fortunate in having been retained upon the same footing as the first, while he has had over the third (who must either retire or accept promotion, and who reasonably anticipated consideration similar to that extended to the first) a prolonged advantage. Will the retirement of the third be insisted upon, while the services of the second are still retained? What is to be the rule for the future?

As pointed out by you, there can be no doubt as to the right and power of the State in the matter, and State considerations are obviously paramount; but I would urge the justice of a grace clause being introduced, which may obviate the sudden and arbitrary incidence of the ruling upon those who, so to speak, to the last moment anticipated no such change. Nor can the question of the disposal of those who have been passed over for promotion be separated from the present issue.

I am, Sirs, your obedient servant,

December, 1889. I.M.S.

*** With reference to the first question asked by our correspondent, it is obvious that as the officers referred to did not decline promotion the rule does not apply to them. With regard to the three cases he has specified, we presume that the first, if again offered promotion, will have the option of acceptance or retirement; the second has not declined, and probably if offered would not decline, promotion; if he did he would be obliged to retire; the third clearly comes under the rule, and we cannot suppose it will be suspended in his favour.—ED. L.

B DISPARAGING PUBLICLY A'S QUALIFICATIONS.

Hypatia.—It is surprising to us that a graduate of the University of Ireland should be so wanting in good taste as to make disparaging reflections on such qualifications as the membership of the two London Colleges and of the Society of Apothecaries. Has our correspondent not been misinformed? This is always the right assumption when an absurd statement is attributed to members of our profession.

Perplexed.—Glen's "Poor-law Orders," published by Knight and Co., will give the information required.

THE EDUCATION OF THE DEAF AND DUMB.

THE Italian Tarra is credited by his compatriots with having initiated and carried a long way to perfection the true education of the deaf and dumb—that is, the substitution for mimicry and "dactylology" of the pure oral method (*metodo orale puro*). Tarra improved on the current Italian traditions in the training of the deaf and dumb, of which there is first authentic notice in the Italy of the sixteenth century. An interesting memoir of this meritorious educationist and man of letters, bearing especially on his services to deaf and dumb children, has recently been compiled by Signor Benedetto Prina.

Tertium quid will find little difficulty in getting British diplomas recognised in most of the States. In New York, however, a local degree must be taken.

THE LATE MR. HAYNES WALTON.

To the Editors of THE LANCET.

SIRS,—The following case occurred some twenty years ago, and may possibly be interesting in connexion with your *résumé* of the late Mr. Haynes Walton, whose skill as an operating "all-round" surgeon was remarkable.

A gentleman, aged about twenty, was driven a distance of three miles to my surgery, having met with the following curious accident. He was intending to start the next week on a shooting tour at the Cape, and, having purchased some new rifle cartridges, was desirous of ascertaining their exact composition, which he attempted to find out in the following manner. Placing one on the top of one of the spikes of an iron railing, he smashed it with a blow of a hammer. The result was an explosion, and he felt a sharp blow on the inside of the middle of the thigh. A small triangular cut in the trousers was noticed, and the skin of the thigh was cut through in the same manner. There was no hæmorrhage, but it was thought best for him to "see a doctor." I passed a probe into the small wound, which was not deep enough to admit the finger, but could not get it in any direction through the cellular tissue, and the patient felt no inconvenience in any way. I could not detect any foreign substance whatever by pressure, and therefore advised him to rest it for twenty-four hours, and wait results. The external wound had healed the next day, and he started for his own home at Durham (some 200 miles), taking Shrewsbury *en route* for the night. The next thing that I heard was that on arriving at Durham inflammation had set in, and a fortnight afterwards Mr. Haynes Walton, who was staying at Durham, was called in. I shortly afterwards received the following letter from him:—

"1, Brook-street, Hanover-square, March 10th.

"MY DEAR SIR,—I was called in on Monday last to see Mr. ——. I found diffuse suppuration extending up the thigh, and a very copious discharge from the wound. I enlarged the wound, and passed my finger upwards and laterally, but discovered nothing. As my finger could not reach to the limit of the suppuration upwards, I passed a probe, and I made an incision through the integuments opposite the end of it, and explored again, but nothing was found. I was able to reach within a couple of inches of the bend of the thigh. I now enlarged the wound a little downwards, and proceeded to search. I then discovered a hole in the fascia. I passed a steel probe and detected metal. I then enlarged the opening, and with a pair of forceps withdrew the entire copper case of the cartridge. It was partly embedded in the bone. In the first instance, I declined to make any examination except under chloroform, and I am sure that I should never have succeeded in removing the body except I had used it. I placed a long splint under the limb in order to prevent all motion. I hear that a very great deal of suppuration followed my operation, with some erysipelas, but that not the slightest constitutional symptoms have appeared. There is no doubt that death would have ensued had the copper not been removed.—Believe me, dear Sir, truly yours, "HAYNES WALTON."

The patient completely recovered, and never attempted again the exploration of a cartridge, except in a more legitimate manner.

I am, Sirs, yours faithfully,

Clapton-common, N.E., Nov. 20th, 1889. HENRY J. BUCK.

A PECULIAR SEQUELA TO GONORRHŒA.

To the Editors of THE LANCET.

SIRS,—Would any of your readers kindly throw light on the following case? A fortnight ago, a young man (aged twenty-eight) came to me complaining of a peculiar musty smell emanating from the testicles, together with scalding pain on micturition. He contracted gonorrhœa two years ago, from which he has never entirely recovered. The discharge ceased more than a year ago, and since then he has been troubled with the smell and pain on micturition. His urine is clear, pale, and abundant. The smell is evident several feet away, and is very pronounced in cold weather; in warm weather it scarcely exists at all. He is otherwise in excellent health and is married. He has one child. Mother and child are healthy. He has been treated with various remedies at different times, both internally and externally—iodide of potassium, outward applications of calomel powdered on the testicles, blackwash, and corrosive sublimate being among the number. He says he has received no benefit whatever from any of them. He has also had bougies passed. I am treating him with nitrate and bicarbonate of potash and attention to diet. I should be very glad of advice as to the treatment of this case.—Yours obediently,

Dec. 7th, 1889. L.R.C.P.

MASON *v.* CHEEVENS.

WE hope to notice the exhaustive report of this case in the *South-West Suffolk Echo* next week.

MEDICAL PRECAUTIONS AGAINST CARRYING INFECTION.

Dr. Turle (North Finchley).—We have read Dr. Turle's letter with much interest, and should be glad to publish one addressed directly to us—and shorter—setting forth the points he very forcibly makes. It will be seen that we do not recognise Miss Cobbe's right to drag the profession into a discussion of details on such a matter in lay newspapers. But it is a very suitable subject for discussion in a medical publication.

Mr. W. N. Walker.—Diphtheria is both contagious and infectious (in the limited sense of the terms)—i.e., the virus may be communicated by actual contact, and indirectly through the medium of air and ingesta.

NURSING IN HONG-KONG.

To the Editors of THE LANCET.

SIRS,—I recently called attention to the statement in the annual medical report on the colony of Hong-Kong that "five French sisters of mercy will shortly arrive as nurses at the hospital." I have since heard the terms on which these sisters have been engaged by the Hong-Kong Government, and they are as follows: The senior sister is to receive seventy dollars a month salary and ten dollars a month in lieu of rations, and each of the other four sisters is to receive forty dollars a month salary and ten dollars a month in lieu of rations. Furnished rooms, fuel, light, and attendance will also be found them, and a room for a private chapel. Of course their passage money to Hong-Kong must be paid by the Government, presumably from Marseilles or Paris, and I suppose they will also receive an allowance for clothing. The Hong-Kong dollar is now worth 3*s.* 3*d.*, so the salaries paid (with ration allowance) will be £156 per annum for the senior sister and £97 10*s.* per annum for each of the others. Now, these are terms on which hundreds of English nurses, trained for three years and upwards in the best English hospitals, would be glad to undertake the work of the Hong-Kong Government Hospital, and I think we have a right to know why the Government of Hong-Kong sends for French sisters of mercy and leaves our own countrywomen out in the cold.—Yours obediently,

Dec. 3rd, 1889. M.D.

AN APPEAL.

To the Editors of THE LANCET.

SIRS,—The professional brother on whose behalf we now appeal was, till October, 1888, making in the practice of his profession an income sufficient to enable him to educate and bring up his children in consonance with the instincts of an educated gentleman, when he was stricken with complete paralysis of the right side, totally unfitting him for any professional work till quite recently. Had it not been for the thrifty and economical habits of himself and his wife, their early removal to a small house, and the timely and generous intervention of some of his professional brethren in Liverpool, he would have been compelled long since to have abandoned his home, and probably his wife and children. Local help having been exhausted, we now appeal to the general body of the profession in the hope of obtaining sufficient funds to enable him to retain his household effects till he is able to follow his profession. His present condition and progress towards recovery justify the belief that he will be able to do so in six months, possibly less. As the British Medical Benevolent Fund has already subscribed £18, his only hope for the future rests with his professional brethren, any of whom desiring further particulars can have them by applying to the undersigned.—We are, Sirs, yours faithfully,

J. D. CRAWFORD (40, Rodney-street, Liverpool).

Dec. 9th, 1889. A. SAMUELS (53, Shaw-street, Liverpool).

ALOPECIA.

To the Editors of THE LANCET.

SIRS,—Can any of your readers having experience of the use of jaborandi for increasing the growth of the human hair give me any formulæ or directions as to the best method of using it in a case of alopecia?

I am, Sirs, yours faithfully,

Dec. 9th, 1889. A. BRENCHLEY, M.D.

ERRATUM.—In Mr. William Bennett's remarks, reported in our last number, upon Mr. Golding Bird's paper on "Sacculations of Veins" at the Pathological Society, for "internal" read throughout *external* jugular.

Clinical Lectures

Delivered to the Students of the

MANCHESTER ROYAL INFIRMARY

During the Summer Session, 1889,

BY THOMAS HARRIS, M.D. LOND., M.R.C.P.,

SENIOR ASSISTANT PHYSICIAN TO THE INFIRMARY, PHYSICIAN TO THE MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT, AND SENIOR DEMONSTRATOR OF PATHOLOGY IN THE OWENS COLLEGE.

LECTURE III.

THE DIAGNOSIS OF THE LATE STAGE OF PULMONARY PHTHISIS.

GENTLEMEN,—In our last lecture we were concerned with the diagnosis of the early stage of phthisis; to-day I wish to speak to you in reference to the diagnosis of advanced cases of that disease. Unfortunately, it is usual to consider three stages of phthisis—the first, or that of consolidation; the second, or that of softening; and the third, or that of excavation. You must however remember that, except in the early stage of the disease, it is very rare to meet with cases of phthisis where the lungs present only one of these changes. Usually all three stages are present in the same lung, one part of the organ presenting the condition of consolidation, in another portion softening has taken place, and in a third we have a cavity of greater or less size at the same time in existence. This fact of all three stages being present at the same time is a consequence of the tubercular process in the lungs not remaining limited for a long period to a single focus. The tuberculosis in an ordinary case of phthisis doubtless commences at one spot, but in a short time, the length of which varies with the acuteness or chronicity of the case, the primary focus gives rise to secondary ones in its immediate neighbourhood. As the tendency is for each of these foci to run through the stages of consolidation, softening, and excavation, you can readily understand how it is that, except in the early stage of phthisis, we find the different stages all present at the same time in one lung. In the acute cases of phthisis these secondary foci are present at an early stage of the disease, and softening and excavation ensue in them at an early period. In the chronic cases, on the other hand, the process remains for a longer time limited to the primary focus, and the secondary foci develop at a later period, whilst softening ensues also more slowly than in the acute cases.

From the above facts you will readily understand why the diagnosis of the last stage of phthisis is usually far more readily made than we have seen to be the case with the early stage of the disease. In the advanced stages we commonly find the symptoms and physical signs of phthisis well marked. But although this applies to the majority of cases, it does not apply to all. We are very frequently surprised to find on the post-mortem-room table much more extensive phthisical changes in the lungs than we had expected, from the result of our clinical examination, to discover. We frequently find that the physical signs do not correspond to the pathological changes in the lungs. We also occasionally meet with cases where the appearance of the patient leads us to expect marked evidences of phthisis, but where, on careful examination of the chest, the indications of phthisis are found to be very much less evident than we had expected simply from the appearance of the person and from the history of the case. And, again, we occasionally meet with cases where the physical signs of phthisis are far more marked over the lower part of one lung than over the apex, and where in consequence we are inclined to regard the case as one of basal phthisis—of phthisis commencing and being most marked at the lower part of the lung. But when we have an opportunity of examining such cases after death, we may be surprised to find that the disease is really much more advanced and of older date in the apex than in the lower part of the lung. We discover in the upper part of the lung cavities—may be of large size—which had given rise to no definite physical signs during life. So that although phthisis can usually be readily diagnosed in its advanced stage, we not unfrequently find advanced stages of the disease in parts of the lungs where they had not been suspected during life, although the chest had been carefully examined. It is a well-recognised fact that phthisical cavities frequently exist without giving rise to signs which allow of their recognition; and it is also true that cavities are very frequently diagnosed without there being sufficient data for such a diagnosis to be made.

We will consider the physical signs which may be present in the case of pulmonary cavities, and we shall find that the cases are rare where absolutely characteristic and pathognomonic signs of such cavities exist. There are especially four conditions which have a very marked influence on the signs which a pulmonary cavity may present. These are the *size* of the cavity, its *position*, the *condition of the surrounding lung*, and the presence or absence of a *free communication with the bronchi*. We will see how each of these conditions may influence the signs presented by a cavity.

The size of cavities varies considerably, and you can readily understand that a cavity the size of a pea is likely to give rise to signs which differ from that the size of a hen's egg. In the former case we have no signs really dependent upon the cavity; what signs are present are the result of the condition of the surrounding lung tissue; whereas in the case of the larger cavity the space would directly influence the physical signs, unless the other conditions (position, condition of surrounding lung, &c.) were unfavourable to the manifestation of those signs. It is not possible to say what size a cavity must be in order that we may recognise it, because the other conditions (position, &c.) may be favourable or unfavourable in any case.

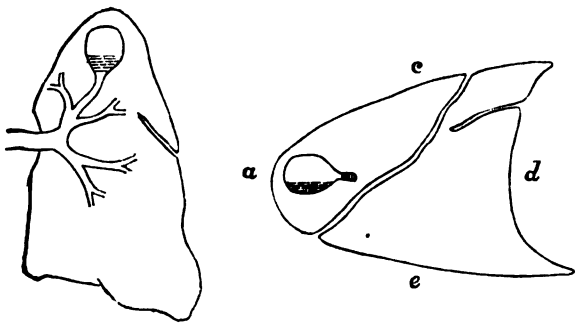
The position of a cavity has a marked influence on the physical signs to which it may give rise. You can readily understand how different must be the physical signs presented by a cavity the size of a walnut, situated immediately beneath the pleura in the apex of a lung, and one of the same dimensions seated in the centre of the lower lobe. In the former case it is directly accessible to percussion and auscultation, in the latter case it is not. The condition of the surrounding lung tissue might likewise be expected, on *a priori* grounds, to have a like influence to the position of the cavity on the physical signs. In the case of a medium-sized cavity surrounded by an extensive area of consolidated lung we usually have the physical signs dependent upon the consolidation rather than upon the cavity. And, again, a cavity surrounded by a small zone of consolidated lung, which alone intervenes between the cavity and the chest wall, is more likely to transmit sounds to the physician's ear and to be affected by percussion than would be the case if the same sized cavity were surrounded by a zone of healthy not consolidated lung.

The influence which the presence or absence of a free communication with the bronchial tubes must exert on the physical signs which a cavity may present will be more clearly understood when we come to speak in detail of the signs of cavities. It will, however, suffice for the present purpose to say that, if a cavity exists in the lungs and is shut off from any communication with the bronchial tubes, there is not likely to be any transmission and modification by the cavity of sounds which originate in the bronchial tubes or higher respiratory passages, such as would be probable if a free communication with the bronchi existed. We will now consider more in detail the various signs which a cavity may present, and also how those signs may be modified according as the above indicated conditions vary.

The chest wall over a cavity is, as a rule, retracted. In some cases the retraction is but very slightly marked, and by carefully watching some cases of phthisis we may see that the retraction, previously existing, may become less marked where a cavity has formed. In some rare cases the chest wall has been noted[1] as more prominent over a large cavity, there being a very slight bulging as compared with the corresponding region of the healthy side. The most common feature, however, to observe on inspecting a chest where a cavity exists is retraction with diminished movement over the affected part.

The vocal fremitus over a cavity varies considerably, as a

[1] Walshe: Diseases of the Lungs, fourth edition, pp. 10 and 423.



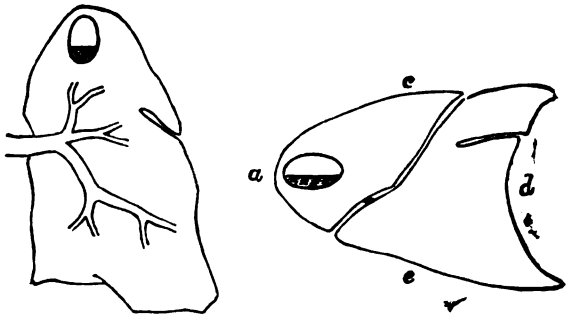
Digitized by Google

rule, in consequence probably of the existence of consolidation around the cavity, it is increased.

The percussion note over a cavity varies remarkably, since so much depends upon the position of the cavity, its size, and the condition of the surrounding lung. If you look at these two preparations you will have little difficulty in understanding the difference which is met with as a result of percussion over cavities. In the one preparation we have a cavity situated at some distance from the pleural surface, and surrounded by consolidated lung tissue. In such a case you can readily understand that dulness on percussion would be the most probable result. In the other preparation you see a large cavity situated immediately beneath the pleura, and can imagine that a probable result of percussion would be not dulness, as in the former case, but hyper-resonance, the note being of a more or less marked tympanitic quality. In many cases of cavities of the lung, probably in the majority of instances, we find only dulness on percussion over the seat of the cavity. This is seen where the cavity is small, and where, even if it is of considerable size, it is surrounded by consolidated lung tissue. On the other hand, some variety of tympanitic resonance is not unfrequently met with as a result of percussion over a cavity. The superficial position of a cavity is favourable to the development of such a percussion note. According to the size and position of a cavity, the note may be distinctly tympanitic, or of only a shallow tympanitic quality. Rarely is a cavity sufficiently large and favourably placed to give rise to an amphoric note. Such resonance is far more frequently associated with pneumothorax than with pulmonary excavation.

A cavity which under one set of conditions gives rise to a tympanitic note may, under different conditions, give

FIG. 1.



A, Vertical lateral section of the lung. B, Vertical antero-posterior section of the lung:—*a*, Apex. *d*, Diaphragmatic surface. *c*, Anterior border. *e*, Posterior.

rise to some alteration in the pitch of that note. One such change is that first pointed out by Wintrich. That observer noticed that the percussion note over a cavity was frequently altered in pitch according as the patient kept the mouth open or closed. He observed that the note became lower pitched when the mouth was closed, and sometimes lower still when the nostrils as well as the mouth were closed. This change in pitch cannot be demonstrated in all cases, since for its production it is necessary that the cavity is in free communication with the bronchi. Where a cavity exists which does not communicate with the neighbouring bronchi, the pitch of the percussion note is the same whether the patient has the mouth open or closed. In some cases the alteration in pitch is only manifest when the patient is lying down, whilst it is not evident when he is sitting up; or it may be detected when he is sitting up, but not when he is in the recumbent posture. This difference, as pointed out by Moritz and Gerhardt, probably depends upon the position in which the cavity communicates with the bronchi and upon the presence of fluid contents in the cavity, which contents are able in one position to occlude temporarily the orifices of the bronchi, but, with an alteration of position of the patient, the contents change position and leave the orifices of the tubes free. Let us suppose that in the case of a cavity in the apex the communication with the bronchi was at the lowermost part of the cavity, as represented diagrammatically in the illustration. (Fig. 1.) If the cavity contained some liquid contents the communication between the cavity and the bronchi would be shut off in the erect posture (A), but there would be a free communication between those parts in the recumbent posture (B) in consequence of the alteration in the position of the fluid contents of the cavity. Consequently, in such a case we should expect no alteration of the pitch of the percussion note when the patient opened and closed the mouth whilst he was in the erect posture, but such an alteration ought to ensue when he assumed the recumbent one. If, on the other hand, the bronchi opened into the cavity on its posterior aspect, instead of below, the condition of affairs would be the exact reverse of the above, and we should expect a change of pitch when the patient was in the erect, but not when he was in the recumbent, posture.

In exceptional instances the tympanitic percussion note over a cavity may be replaced by a toneless note where the space becomes filled with secretion, and that dull note may give place again to a tympanitic one when the secretion is expectorated. In still rarer cases of a large cavity with much secretion simple change of position alters the percussion note, so that a part of the chest which, for instance, was tympanitic in the recumbent, becomes dull when the patient assumes the erect posture. Eichhorst[2] states that in some cases the tympanitic note detected over a cavity becomes higher pitched on a deep inspiration, and lower with expiration. The effect of a deep inspiration may not merely raise the pitch of the tympanitic note, but cause the tympanitic note to be replaced by a dull one (Wintrich). Another sign, which was pointed out by Gerhardt, is in rare cases detected over a cavity. This is the alteration of the pitch of the percussion note by simply changing the posture of the patient, such alteration being a consequence

FIG. 2.

of the shape of the cavity becoming altered by the different position, which the fluid contents of the cavity assumes. You are aware probably that we obtain the same pitch in the tympanitic note by percussing over a cylindrical vessel as over one of an ovoid shape, provided that the orifice of the two vessels is of the same size, and also the length of the column of air contained in them is the same. But if the column of air is shortened in either vessel, then the pitch of the percussion note which can be obtained by percussing over the orifice of that vessel is raised. A similar condition has been found by percussing over cavities. If there is an oval-shaped cavity in the apex of a lung, the long axis of the cavity corresponding to the long axis of the lung, and if that cavity contains a medium quantity of fluid contents, the length of the column of air, which has an influence on the pitch of the percussion note, will be greater in the recumbent (Fig. 2, B) than in the erect posture (Fig. 2, A). And consequently the pitch of the note will be higher when the patient is in the erect than when in the recumbent posture. If, on the other hand, the oval-shaped cavity has its long axis running in an antero-posterior direction, and not corresponding to the long axis of the lung, then the pitch of the tympanitic percussion note, which may be elicited over it, will be higher when the patient is in the

Digitized by Google

recumbent (Fig. 2, it thus when he is in the erect or sitting bronchial type) or complete closure over a cavity, even of position. Now, this percussion over a cavity may reveal considerable size, may be rendered impossible by the accumulation of the pleural effusion, by the presence of a large number of clots. The same is true of the auscultatory phenomena. Under ordinary circumstances, when the cavity is empty, it is emptied by coughing, and is filled with air at each inspiration, we have the typical amphoric breathing, with or without metallic tinkling, a phenomenon which is rarely met with over a solid lung, and which is therefore of great importance in the diagnosis of pyo-pneumothorax. Instead of such an obscured condition of the percussion note, we have a tympanitic note, and the auscultatory phenomena are those of large cavity with a free communication with the bronchi, and of a cavity filled with air and of gurgling character. The large bronchial tubes, the cavities, the lung space, were so large that the cough could not produce sufficient force to empty the cavities even of blowing and loose breathing. The cavities arise from of blowing and loose breathing. The cavities arise from the breaking down of the pneumonic exudation, and the breath sound of the pneumonic cavity rather than the cavernous breathing, or the amphoric breathing, or the bronchial, tubular, cavernous, etc., is more any case of pneumonic consolidation, and the presence of a cavity rather than the presence of the consolidation is proved by the existence of a pneumothorax, which is rarely met with over a solid lung. Now, however, they do, and we have had a case in which we were almost certain by case of pulmonary tuberculosis, and over other portions over the upper lobe of the lung, but we also found that the auscultatory phenomena were those of a cavity, and that the cavity was filled with air at each inspiration. Under ordinary circumstances, with or without metallic tinkling, a cavity is not easily made sure a pulmonary cavity, but in this case there was a pneumothorax, which made it almost certain that the cavity was a pulmonary one. Such a case I may add, is enough to show that the presence of a pneumothorax does not always indicate the presence of a cavity, it has been described as being present in cases

to these signs. They are more frequently audible over hydro-pneumothorax or pyo-pneumothorax than over large excavations in the lung substance.

It will be thus seen that there are but few signs which when present are conclusive evidence of the presence of pulmonary cavities, and also that very frequently pulmonary cavities exist without giving rise to signs which are pathognomonic of their existence. We need to carefully bear in mind that simple consolidation of the lung often gives rise to signs which are mistaken for those associated with the existence of cavities. As a rule, however, although the diagnosis of the presence of a cavity is difficult, we are able to say whether the destructive changes in the lung in a particular case are advanced or not; but in some cases we are unable to be certain even on this point, because very extensive destruction of the lungs may be present, and yet give rise to very insignificant physical signs. Another point of considerable importance bearing on this same subject is the fact that in advanced cases of phthisis we may have the physical signs much more marked at the base than at the apex, and yet when we have an opportunity of examining such cases after death we find that the disease is much more advanced at the apex than at the base. Such cases are very apt to be mistaken for cases of primary basal phthisis; but in reality they are only cases where the signs of the cavities in the upper parts of the lungs are few and indefinite, whilst the signs of those existing at the base and of the softening which is taking place there are more evident. Cases of basal tubercular phthisis—i.e., phthisis commencing at the lower part of a lung—do occur, but they are probably more rare even than is supposed.

ABSTRACT OF

The Harveian Lectures

ON THE

SURGERY OF THE KIDNEYS.

Delivered before the Harveian Society of London,

By J. KNOWSLEY THORNTON, M.C.,

SURGEON TO THE SAMARITAN FREE HOSPITAL.

LECTURE III.

MR. PRESIDENT AND GENTLEMEN,—I have now arrived at a very important branch of my subject—renal tumours. Of osteomata and hæmatangiomata I have nothing to say; the very occurrence of true bone tumours is doubtful, and the small vascular tumours, which resemble telangiectasis of the liver, have never been seen of sufficient size to render them surgically important. The simple fibroma often attains a great size, and so do the mixed forms. The fibro-cyst, which furnishes the largest specimens, is probably always a degenerative form of the simple fibroma, the cavities being the result of breaking down of central portions of the growth. The tumours in which there is an admixture of muscular tissue also attain an enormous size (myo- or rhabdo-fibroma). Those in which fat is present are, like the cystic tumours, products of degenerative change in the simple fibroma; they often also attain a very great size. Fatty transformation of the kidney, as recorded by various pathological observers, is a totally different condition, due to increase of fat in the adipose-areolar tissue, which pushes its way into the kidney through the hilum; it is usually the result of suppurative disease in one kidney. Its only surgical importance arises in a case in which the other kidney becoming the seat of some disease, curable by surgery, the patient practically only has one kidney, and the surgeon should be able to recognise the fatty transformation of the opposite organ by abdominal exploration. Nothing is known as to the causes, and but little as to the symptoms, of these simple tumours; they probably produce no symptoms till their size becomes a source of discomfort, or a cause of damage to the affected or to neighbouring organs, by their weight and pressure. Their recognition must chiefly depend upon their evident connexion with the kidney, their slow growth, and the absence of symptoms above referred to. When they attain a sufficient size to make them a serious inconvenience, a source of danger to the kidney they are attached to, or to other organs, they may be removed by abdominal section, either with or without the kidney from which they grow, according to the closeness of their connexion with the organ.

Adenomata are of two kinds, the papillary and the glandular; the former commonly projects from the lining membrane of the tubules and Malpighian capsules; the latter is more common in the cortex. It is very rare for either to attain a size to call for surgical interference. I have put them in a group by themselves, because their minute structure closely resembles that of the ovarian adenomata, and these latter growths are certainly on the borderland of malignancy. I have operated successfully in a case of hydronephrosis, associated with calculus, both lesions being produced by a papilloma growing at the pelvic end of the ureter. Sarcomata are not only among the commonest of renal tumours, but also the most varied in their clinical characters, some being so malignant that they should never be touched, while others are so slow in growth, so slow in invading neighbouring parts, and so slow in recurring, if they ever do recur, that they present the most favourable cases for successful surgery. Renal sarcoma is commoner in children than in adults, and is also usually in them of a very malignant type. I have never myself operated upon a child for renal sarcoma. I have refused to do so several times, and I have seen several such operations, and each has impressed strongly upon my mind the uselessness of the procedure. With adults the exact reverse seems to be the case; in them renal sarcoma is often of slow growth, is slow in invading neighbouring tissues, and is also slow in recurrence. The difference is to be sought, first, in the varieties of sarcoma most common in early life and in the adult; and, secondly, in the portion of the organ first invaded by the disease. In children the cell element predominates, while in adults there is a large amount of dense intercellular substance. In children the whole organ is much more often infiltrated, while in the adult the disease commonly attacks the capsule, leaving often the secreting structure uninvaded. Of the five adults I have operated upon for sarcoma three recovered and two died. Four of the patients were females, aged respectively fifty-three, twenty-five, forty-two, and thirty-six, and the fifth was a male aged twenty-two. In one of the cases the tumour was large, and had not involved the kidney at all; it had been suggested that it originated in the supra-renal capsule, but against this was the fact that the capsule of the kidney was continued over the surface of the tumour. My first fatal case was a cysto-sarcoma, weighing ten pounds, of mixed kind, containing round cells, myxomatous tissue, and many bloodvessels, occurring in a woman aged twenty-five; it had penetrated the diaphragm and pleura. The second was that of a married woman, aged forty-two, and the growth was a spindle-celled sarcoma commencing in the capsule near the hilum, and invading the interior of the pelvis. The history of the first of these cases is sufficiently long to make it probable that an early operation might have saved her. In the last case the slow growth, with no sign of infection of other organs, in spite of the early hæmorrhage, shows, I think, clearly, that a successful result would have attended operation, at any time before the kidney became fixed by extension of the growth into the surrounding structures, and the health broken down by repeated hæmorrhages and constant suffering.

If we now attempt to summarise our imperfect knowledge of renal sarcoma, we find that it is most common in children, is in them often congenital, in this case going on to a rapidly fatal termination, from quick increase in size, involvement of neighbouring tissues and organs, and general marasmus; that when it makes its appearance later, but still in childhood, it runs a much more rapid course than in the adult, more speedily involves surrounding tissues, and is therefore rarely seen at a time when operation can be undertaken with any reasonable chance of completely eradicating the disease; that even when detected quite early, and before there is any sign of its having involved the other tissues, its removal is commonly followed by such speedy recurrence that the operation is barely justifiable. Such recurrence, moreover, is very extensive in its outbreak, and usually leads to an amount of suffering altogether beyond that which is seen when the disease is allowed to run its natural course in the kidney. Turning now to the adult, we find that the disease is most common in the

Digitized by Google

middle period of life, is usually slow and insidious in its early course, and frequently progresses slowly, and often painlessly, for years, before it spreads beyond the kidney; a certain amount of aching and pain in the situation of the affected kidney, occasional attacks of hæmaturia, and a hard swelling in the renal region, which is from its weight apt to become more mobile than a normal kidney, and is therefore likely to be regarded as an innocent condition, being the only symptoms which are at all common. It is worthy of special note that with two large tumours of the capsule (or of the supra-renal capsule) there was no hæmorrhage; indeed, the only symptom in each case was the tumour, till its size caused indigestion, nausea, &c. There was never any urinary symptom in either case to direct attention to the kidney. The tumours most likely to be mistaken for renal tumours are retro-peritoneal cysts, often quite impossible to diagnose from hydronephrosis, omental cysts, distended gall-bladder surrounded by adhesions, enlarged spleen, ovarian tumour, subperitoneal fibro-myoma and solid sarcoma of mesentery, and retro-peritoneal tissue. Lymphadenomata, though not uncommon in the kidneys, are always a part of a general disease, and, except in the matter of differential diagnosis, quite outside the province of surgery. Of carcinoma, the encephaloid variety is most common, then the scirrhous, then the colloid. Epithelioma and cylindroma are so rare as to be almost curiosities. We have, of course, nothing to do with the secondary forms of the disease, which attack both organs, but only with primary cancer affecting one kidney. This is not nearly so common as sarcoma, and is essentially a disease of the adult, and occurs chiefly in people past middle life. The causes appear to be heredity, the long-continued irritation of calculus, accidental blows, and injuries. The symptoms are a combination of those of calculus, of those of the early stage of tubercle, and of those of sarcoma. I think Newman puts it well when he says, "The differences in the symptoms of sarcoma and those of cancer will be found to be one of degree rather than of kind." Renal carcinoma frequently infiltrates the whole organ, but it also occurs with the appearance of a capsule; this is, however, deceptive, for microscopic examination shows that there is a gradual transition from the cancer to the healthy renal epithelium, extending through the apparent limiting capsule. This was well seen in the only case of primary cancer that I have met with, in a widow aged fifty-three, from whom I removed a kidney affected with encephaloid cancer. Adding this case to the sarcoma cases, I have six operations for malignant disease, with four recoveries and two deaths. Lumbar nephrectomy is essentially the same operation as lumbar nephrotomy, but with the addition of the enucleation and removal of the kidney through the lumbar incision. The objections to it are: 1. The small space available for incision in most cases. 2. The danger of wounding a pleura with a low insertion. 3. The danger of wounding the colon or the peritoneum, and of fouling the latter without being aware of the accident. 4. The possibility of not being able to find the kidney at all, an accident which has happened in a large number of cases, and to experienced London surgeons. 5. The possibility of removing a single kidney, without knowing that the patient has only the one. 6. The impossibility of noting the condition of the other kidney and ureter. 7. The fact that it is only suitable for a limited number of cases, it being impossible to remove much-enlarged kidneys, through any incision that can be confined to the loin. I have only once performed the operation, and then under peculiar circumstances. I had made a median abdominal incision to explore the pelvic contents, and found a disorganised kidney. It was impossible to remove it through this median incision without extending it to a great length, and so, having opened the kidney through the loin to explore its interior, I extended this into the usual lumbar incision, and thus removed the kidney.

The great point advanced in favour of lumbar nephrectomy is that up to the present time it has been more successful than the abdominal method; but this is because the latter has usually been a last resource in cases too bad to be operated on by the lumbar method. There are, however, some conditions in which the lumbar operation may properly be performed, notably cases in which a lumbar incision and drainage having failed, the extirpation has to be undertaken with a fetid sinus, already extending from the loin into the interior of the kidney; also in some cases of wound of the kidney, to which I shall refer later. For the performance of lumbar nephrectomy various operators advise various incisions, but each case must really be dealt with on its own merits, according to the size of the kidney, the absence or presence of adhesions, and the configuration of the individual. When the kidney is thoroughly exposed, it must be enucleated from its adipose areolar capsule, or from its true capsule, according to circumstances. When reached the vessels should be tied as close to the kidney as possible, *en masse* if they are normal, and separately if they are more numerous. The ureter should, whenever possible, be loosened from its bed, secured with forceps close to the kidney, and then ligatured further off, a sponge being placed under it when it is divided between the forceps and ligature, in case a few drops of its contents should foul the wound. Its free end should be fixed in the lips of the external wound by a suture, or safety pin, a rubber drainage-tube or two being placed alongside of it, and the wound closed round their mouths by a few points of interrupted suture, each including all the divided tissues. Before the sutures are introduced, the wound should be well dried with carbolised sponges, and then flushed with some warm antiseptic solution. If the adhesions round the vessels are very dense—sometimes they are like cartilage,—they must be carefully snipped through, bit by bit, with scissors, and the vessels tied together with some of the adherent tissue, rather than risk wounding the aorta or cava by too carefully dissecting them out. A large, thick, absorbent, antiseptic dressing, secured by broad adhesive straps, or by a many-tailed flannel bandage, is then applied. The vertical incision which I suggested in 1883, so as to avoid opening the peritoneum, I have found in practice not to answer.

Abdominal nephrectomy should be performed by the lateral incision introduced by Langenbuch, and made along the outer border of the right or left rectus, according to the kidney to be removed, as it not only gives a more easy command of the renal vessels and ureter; but it avoids almost entirely exposure of the intestines and general cavity of the peritoneum during the operation, and it gives easier access to the outer layer of the mesocolon, through which the kidney should be approached in order to avoid the vessels, which lie chiefly in the inner layer; thus by operating through the outer layer hæmorrhage is avoided, and the vascular supply of the colon is less liable to injury. The incision should begin just below the ribs, a narrow hand's-breadth from the middle line, and be carried down for about four inches, so as to admit the operator's hand without bruising the parietes. As soon as the peritoneum is open, the hand should be introduced and passed over to the opposite side of the abdomen, for the examination of the opposite kidney and ureter. A flat carbolised sponge is then introduced, to keep back and cover the intestines; a small opening is made in the outer layer of the mesocolon, and enlarged by tearing, and through this opening the size and condition as to adhesions of the kidney are estimated. When it is found that the tissues lying above the kidney are normal, the fingers can be gradually insinuated under the peritoneal covering till the aorta is reached; from it the renal artery can be traced, and then the vessels can be ligatured before the kidney is enucleated, but when, on the other hand, there is much inflammatory thickening of the tissues and adhesion, the kidney must be enucleated before the vessels can be reached and cleared. In old-standing cases of pyelitis or pyonephrosis the adhesions about the vessels and hilum are often extremely dense and thick, so that the renal vessels can only be discovered when they are cut across and bleed, and can only be secured by running a needle armed with silk under their mouths in this dense tissue. When I can I transfix and tie the vein and artery separately; in other cases I pass the silk through some part of the tissues above the vessels and tie *en masse*. I usually apply a separate fine ligature around the whole pedicle before dropping it. During enucleation each bleeding vessel should be secured by a pair of small pressure forceps, and well wrung sponges should be pushed down between the kidney and the capsule as successive portions are enucleated. The last part to separate is the ureter, and before separation its renal end should be secured by pressure forceps, then a ligature tied a little way from the forceps, and a sponge placed under it before it is divided. Whenever it is possible I enucleate it for some distance from the kidney before dividing it, so that its cut end, with the sponge under it, may be at once drawn outside the abdomen; and I afterwards fix it in the lower angle or most convenient part of the abdominal incision with a cleansed safety pin. The vessels having been secured, the sac should be carefully

Digitized by Google

sponged out. If a well-wrung sponge, pressed to the bottom of the sac, comes out fairly dry and but little blood-stained, and if the operator is absolutely certain that no fouling of the sac has occurred with the kidney contents, its edges may be allowed to drop together, and the abdomen closed without drainage. It is not advisable to suture the edges of the sac. If there is fear of oozing, or the least doubt as to the perfect asepticity of the operation, it is better to drain with a Keith's glass tube, projecting from the abdominal incision with sponge dressing, and clearance every twelve hours under the spray. If a loin opening has also been made, a rubber tube should be placed there. I treat the cases after operation exactly as I treat all other abdominal operation cases, except that I allow no opium in any form, and I avoid stimulants also. When a sedative is absolutely necessary, I give bromide of potassium and chloral, in rectal injections. Sickness I treat at first with fifteen-grain doses of oxalate of cerium in mucilage, frequently repeated; but if it continue beyond the third day, I give a few doses of white mixture, and aid its action by a small enema, and this is generally efficacious. In the absence of vomiting, I keep the bowels quiet for a week, as any disturbance in the colon must affect the intra-peritoneal wound injuriously. I now treat the ureter with tincture of iodine, then with strong corrosive sublimate lotion, and in some of the cases it has after this remained sweet, and healed quickly. The occasional absence of a second kidney, the knowledge that in one case at least (Polk's) a single kidney has been removed, the error only being discovered after the death of the patient, the importance of knowing exactly the condition of the other kidney and ureter, and the greater convenience and precision of the abdominal method, seem to me to indicate its use in all but some exceptional cases, to which I have already referred. I do not advocate the performance of abdominal nephrectomy by every tyro in surgery, neither do I recommend such to undertake any serious abdominal operation; but I do unhesitatingly affirm that, as a precise and scientific operation, there is no comparison between the abdominal operation and its lumbar rival.

In reference to the examination of the urine, I do not attach so much importance to the secreting power of the other kidney as is done by most writers on renal surgery. Still, it is well to have the urea estimated several times before operation, taking the whole quantity of urine passed in each twenty-four hours. Low specific gravity, constant presence of albumen to any amount, and, worse still, the presence of casts, are indications not to be neglected. With regard to the contrivances for obtaining the urine from one ureter, I believe they are all nearly, if not quite, as dangerous as a properly performed abdominal nephrectomy, and I leave it to those who believe in these aids to surgery to learn their use from other sources.

Injuries of the kidney and of the ureter only require to be treated on sound surgical principles to yield a very large proportion of success. The kidneys are liable to be bruised, shaken from their normal seat, crushed, ruptured, torn, cut, and penetrated by shot or bullet. The ureters are liable to be violently stretched, torn across, or to have holes made in them by knife, shot, or bullet. They are also liable to be damaged by the surgeon, in the performance of abdominal operations, and by the accoucheur, in delivery by the forceps. Most of these injuries may occur, both to the kidney and to the ureter, without external wound; others, such as those inflicted by stab or gunshot, always have an external wound, to guide us to the seat, and as to the probable extent of the injury. The mortality from traumatic lesions corresponds very closely to that following surgical procedures for the various diseases we have been considering. Let us hope that, as my results in abdominal nephrectomy show a reduction of mortality to 20 per cent., so in the new era which has dawned upon abdominal surgery a like reduction may occur in the mortality from traumatic lesions. Bruises of the kidney may lead to abscess, but the presence of organisms is necessary to the development of the latter. Peri-nephric suppuration may originate in the same way. Crush of the kidney is one of the more common traumatic lesions, from the frequency of cart or carriage-wheel accidents; in this case the kidney may be merely bruised or contused, or, it may be seriously lacerated; in either case blood may appear in the urine. Or it may be altogether separated from its vessels and ureter, a condition which would be indicated by much more severe and complete collapse, by evidences of internal hæmorrhage, by diminution of the quantity of urine, but not necessarily by the presence of blood in it, as the torn ureter quickly contracting and curling over, no urine or blood may pass down it, from the moment of the accident. If such a condition were suspected, the abdomen should at once be opened and searched. If, on the other hand, only the parenchyma of the organ is injured, there is every probability that, with rest, cold applications, and proper care, the patient will recover. The bleeding tends to cease spontaneously; and if the kidney is healthy at the time of the accident, the urine will not necessarily trouble the peritoneum. Of course, if an accident should happen to a kidney already diseased, and pyoid or putrid urine flow either into the cellular tissue or peritoneum, the results would be immediately disastrous; in the latter case probably the most speedy surgery, and flushing out and drainage of the peritoneum, would hardly save the patient. If in rupture of the kidney healthy urine escape backwards into the cellular tissue, the condition known as acute hydronephrosis is produced. Sympathetic suppression of urine may result from any of these renal injuries, but more commonly follows bilateral than unilateral injury. When it is present, the surgeon has to consider the possibility of both ureters being torn across. If a clot of blood obstruct the ureter after injury to the kidney, renal colic may be added to other symptoms. Collapse, vomiting, hæmaturia, retraction of testicle, fulness and tenderness in the flank, ecchymosis of the skin over the kidney, and possibly suppression of urine, are the symptoms of serious injury.

Penetrating wounds of the kidney, from loin stab, have not been uncommon, and the literature of the subject shows that the kidney, or a portion of it, is apt to prolapse through the wound, and that the patients are very likely to recover when left to nature, or treated on the rough principles of the past. If there is the least reason to conclude from the symptoms that adjacent organs are implicated, the abdomen should be at once opened, the site of the injury thoroughly explored, the peritoneum cleansed, and any other necessary procedure adopted. In deciding on the proper treatment to follow in any given case of renal injury, the chief points to attend to are the evidences of injury of other organs, the evidences of internal hæmorrhage, the evidences of internal escape of urine, and the possibilities of recovery, as evidenced by the general condition of the patient, if simple rest and care be the treatment. Wound of the ureter may lead to acute hydronephrosis, and may be treated by immediate incision and drainage, and by more remote nephrectomy if a fistula result; or if there be reason to suppose that the wound is small, it may be exposed and sutured, or the injured part of the ureter may be resected, and the healthy parts of the tube sutured together.

In gunshot wounds each case must be treated solely on its own merits. It must never be forgotten that in any renal injury the accumulation of blood and urine in the cellular tissue around the ureter may, by its pressure, obstruct that passage, and the possibility of obstruction to the flow of urine, by accumulation of blood-clot in the bladder, must also be borne in mind.

Gentlemen, with this hurried sketch of the nature and treatment of the traumatic lesions of the kidneys and ureters I close my lectures. No one is more conscious of their imperfections than myself. The subject has grown, and is growing so rapidly with increased experience, that it already requires at least a dozen lectures to do it justice. I have endeavoured to make these lectures as practical as possible, illustrating by my own cases, and stating frankly my own opinions, rather than searching for those of others, and giving you a compilation. I can only say, in conclusion, that if you, who have so kindly and patiently listened to me, have learnt one-half as much, or derived one-half the pleasure from listening, as I have found in the preparation, I am amply repaid for my labour.

WOLVERHAMPTON HOSPITAL SUNDAY FUND.—Alderman Wm. Edwards presided at the annual meeting of clergymen and ministers held at the Town Hall on the 12th inst. for the purpose of forming a Hospital Sunday Committee for the ensuing year. A committee was appointed. The total Hospital Sunday collections for 1889 were stated to be £624 14*s.* 9*d.*, a decrease of £14 on the year.

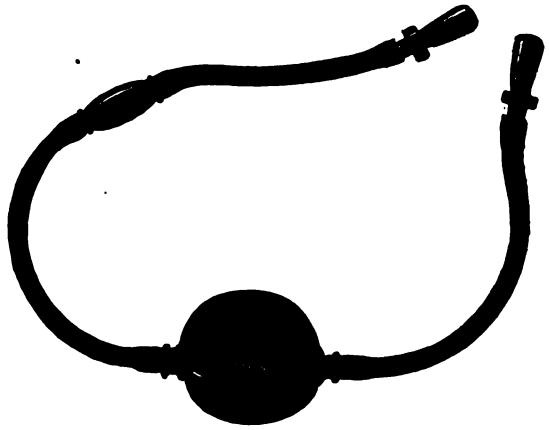
CHOREA AND RHEUMATISM.

BY H. WALTER SYERS, M.A., M.D. CANTAB., M.R.C.P.,
PHYSICIAN TO OUT-PATIENTS, GREAT NORTHERN CENTRAL HOSPITAL.

THE wide divergence of opinion concerning the relationship between acute rheumatism and chorea as cause and effect is well known. While, on the one hand, many observers maintain the existence of the closest connexion between the two maladies, asserting, indeed, that of all the causes of chorea rheumatism is most efficient; others, on the contrary, hold that this connexion has been greatly over-estimated, and that the cases of chorea which can be properly attributed to acute rheumatism as their cause are comparatively few in number. This being the case, it may be of some interest to record the result of an analysis of 146 cases of chorea observed at the Westminster Hospital during seven years (1881-87), in which series the actual relationship of the chorea to acute rheumatism (along with other matters) was accurately noted. The cases are given in detail in the Westminster Hospital Reports for the years mentioned, and from the summary which I prepared for the last report the following figures are largely drawn.

I have analysed these 146 cases of chorea with the object of ascertaining the percentage of cases which could be fairly ascribed to acute rheumatism as their cause. All these cases have been taken with great care and the facts most thoroughly sifted. Of the 146 cases only 9 (6·16 per cent.) could by any possibility be attributed to acute rheumatism as their cause. That is to say, rheumatism immediately preceded the attack, or the latter occurred during convalescence from acute rheumatism; whilst all other possible causes of chorea were entirely absent in only 9 cases. In 11 cases the attack of rheumatism occurred during the course of the chorea; in 15 cases acute rheumatism had occurred at some more or less distant period, the interval varying from six years to one month. Thus, some sort of relationship other than causal existed between the attack of chorea and the acute rheumatism in 26 cases, the total number of cases having any rheumatic antecedent being 35, or 23·97 per cent. A rheumatic inheritance existed in 47 cases, 32·19 per cent. The causes assigned by the friends in 94 cases (64·38 per cent.) was nervous strain (fright, distress, and school overpressure). As regards the condition of the heart, in 20 cases a persistent systolic murmur was audible at the apex, and of these 20 cases 11 had suffered from acute rheumatism previously. A murmur, constant neither in force nor rhythm, was audible over the region of the apex in 64 cases, this murmur entirely disappearing as the patient recovered. The number of cases having a neurotic inheritance was a trifle larger than that owning a rheumatic inheritance, the former being 49, the latter 47. There was an inheritance of phthisis in 14 cases and of gout in 4. As regards age, only 3 cases were under eight; between five and ten, 34 cases; between ten and twenty, 96 cases; between twenty and thirty, 10 cases; between thirty and forty, 1 case; between forty and fifty, 1 case; between fifty and sixty, 1 case. As regards the relationship as cause and effect between acute rheumatism and chorea, the figures given above agree with the results obtained by Dr. Sturges, who gives from 5 to 8 per cent. as the average of cases of chorea arising directly from acute rheumatism. In only twenty cases (13·69 per cent.) was there evidence of damage to the endocardium, yet I find from analysis of cases of acute rheumatism that between the ages of ten and thirty 27·7 is the percentage of cases having cardiac disease due to acute rheumatism. Should the ordinary teaching on the subject be correct, it is surely strange that acute rheumatism at the very age when the heart is most liable to be affected should in the case of chorea cause such affection in barely half the number of cases. It is still commonly stated in the text-books that rheumatism is one of the most efficient causes of chorea, yet several recent observations tend to results opposed to this view. No doubt the frequent presence of a cardiac murmur has led to the assumption of valvular disease, and of previous acute rheumatism, without care having been taken to ascertain whether the murmur was constant and invariable. As stated above, a fleeting murmur was audible in 64 of the cases analysed; but in every one of these cases it had disappeared at the time of the discharge of the patient, and there was no reason whatever to believe that in any one of the cases the heart was damaged. Probably, were sufficient pains taken to investigate thoroughly the history of a series of cases of chorea, similar results would be obtained; but so long as vague pains in the limbs are admitted as evidence of rheumatism, and the mere presence of a murmur is considered satisfactory evidence of cardiac disease of rheumatic origin, for just so long will the ordinary views as to the intimate connexion between chorea and acute rheumatism be maintained. The number of cases having neurotic inheritance—49, or 33·57 per cent.—is greater than that having any other traceable inheritance. The large number of cases—94, or 64·38 per cent.—in which the disorder originated in some nervous disturbance (overwork at school, distress, shock), very significantly points to nervous stress of some sort as the most efficient cause. With regard to the other points brought out in the analysis (sex and age) comment seems unnecessary, as the results agree with facts already sufficiently well known.



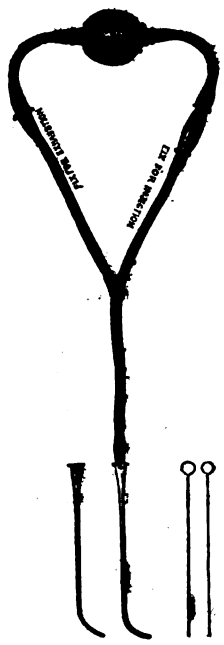
The following results were obtained:—146 cases of chorea: Acute rheumatism, as cause, 6·16 per cent.; rheumatic antecedents, not causal, 23·97 per cent.; nervous disturbance, as cause, 64·38 per cent.; rheumatic inheritance, 32·19 per cent.; neurotic inheritance, 33·56 per cent. Heart: Structural heart disease, 13·69 per cent.; heart affection other than structural, 43·8 per cent.

NEW AURAL INJECTOR AND EXCAVATOR, WITH A FLEXIBLE EUSTACHIAN CATHETER.

BY JOHN WARD COUSINS, M.D. LOND., F.R.C.S.,
SENIOR SURGEON TO THE ROYAL PORTSMOUTH HOSPITAL, AND PORTSMOUTH AND SOUTH HANTS EYE AND EAR INFIRMARY.

SINCE the publication of my paper on Tinnitus Aurium, and its Treatment by a New Method of Alternate Injection and Evacuation of Air, I have considerably modified my apparatus, and have now adapted it for self-application. It consists of one hand-ball fitted with a recoil spring, which increases the force and rapidity of its expansion. (Fig. 1.) The injecting and evacuating tubes both terminate

FIG. 1.



in a vulcanite joint, to which a nasal piece of soft rubber can be attached. The nasal pieces are made in different sizes, and several of them are supplied with each instrument. When medicated air is to be used, the volatile substance must be dropped upon a pledget of cotton-wool, placed in the vulcanite box, which is fixed on the injecting tube. In this way I use choloroform, ether, creasote, pinol, and many other remedies. For the successful application of the treatment, it is essential that the patient should be instructed to practise injection and evacuation of the tympanum in the following manner: The nasal orifices must first of all be carefully wiped dry, and the nose pieces adjusted, *so as to securely and completely plug the nostrils.* The nasal tubes are now held in position by the forefinger and thumb of the left hand, and the hand-ball

Digitized by Google

is elevated and compressed by the right, and then allowed to expand by its own elasticity. During the steady performance of these movements the patient should take a full inspiration, and while holding the breath and pressing the lips together, he should make an expiratory effort, just as if he were in the act of blowing through a tube. With many patients the entrance of air into the tympanic cavity is rendered easy by the act of deglutition, for the muscular movements of the pharynx act directly upon the open ends of the Eustachian tubes. As a general rule, my patients require very little instruction, and soon become very skilful with the instrument. The alternate method presents many advantages over other forms of tubal inflation. It promotes the drainage of the tympanum and the discharge of pent-up fluid into the pharynx. It also proves of material assistance in cases of collapsed and adherent membrane. Its daily application is especially useful in the treatment of tinnitus aurium caused by abnormal tension, and also in other forms of chronic middle-ear disease. The apparatus for alternate injection and evacuation with the Eustachian catheter is represented in Fig. 2. The tubes are joined together, and near their junction a vulcanite terminal is fixed for the insertion of the catheter. The flexible catheter is a flattened tube of soft metal, and it can be readily bent to any shape by protecting the bore with the stilette. (Fig. 2.) For the successful application of the Eustachian catheter, it is often necessary to adapt the instrument to the curvatures of the nose and pharynx. Sometimes the nasal passages are by conformation irregular, or they become tortuous and obstructed by morbid changes in the bone or lining membrane; in other cases the position of the tubal orifices and mucous folds of the pharynx require a special flexion of the beak. For some patients I keep a catheter always bent and ready. The instrument must be carefully washed and deodorised after each operation. In performing the operation of alternate injection and evacuation of the tympanic cavity, the hand-ball must always be attached to the catheter after its introduction. The surgeon should elevate and compress the hand-ball with the right hand, and hold the catheter and close the nostrils with the left. At the same time he must direct the patient to practise the movements already described. During the expansion of the hand-ball the catheter should be drawn outwards for half an inch, for by this manœuvre the evacuating power will be increased. Special care must be taken to prevent twisting or kinking of the indiarubber tubes. Sometimes the point of the catheter gets lodged in the folds of the pharynx, so that the injection of air is obstructed. When this occurs, the instrument should be rotated a little, and then replaced over the Eustachian orifice. If from any cause considerable difficulty is experienced in passing the flexible metallic catheter through the nasal meatus, I substitute for it a fine vulcanite instrument, which can be bent to any curve by gentle heat.

FIG. 2.

In conclusion, I desire to mention that all the instruments described in this paper have been made for me by Messrs. Maw, Son, and Thompson, of London.

Southsea.

DEATH FROM AN OVERDOSE OF MORPHIA.—The death is announced of Mr. Harwood Casson, physician and surgeon, of Worksop, Notts, under painful circumstances. The coroner's jury returned a verdict of "Death by misadventure from an overdose of morphia, taken to relieve neuralgic pains." The evidence showed that Mr. Casson had been a martyr to neuralgia, and could not obtain sleep without morphia. He also suffered from Bright's disease. The foreman, on behalf of the jury, expressed a feeling of deep sympathy with the widow and family.

FRACTURE OF SKULL THROUGH ANTERIOR FOSSA (?); SYMPTOMS OF COMPRESSION; TREPHINING; RECOVERY.

BY F. H. WIGMORE, M.B. CANTAB.

W. W——, about thirty years of age, a tailor by trade and not a sober man, fell down a flight of stairs backwards on the night of April 23rd. I did not see him until May 6th, fourteen days after the injury. The history I obtained was as follows:—The scalp was slightly cut and bruised (scar seen on shaving the head) on the left side about half an inch above the superior curved line. His nose bled, and he was stupid like one suffering from concussion of the brain. From the date of the injury he became gradually unconscious, his articulation imperfect, and he spoke for the last time on May 4th. On May 5th urine and fæces passed incontinently. On the 6th he had two slight "fits" in the morning. When I saw him that night he was in a state of stupor, not so deep but that he could be made to open his eyes and mouth, though not to protrude the tongue. He had a slight fit while I was with him; the left arm and hand alone affected and drawn towards the middle line of the body. The pupils were natural and reacted to light. Temperature normal; pulse 100. Ten grains of bromide and iodide of potassium every four hours and a sinapism to the back of the neck were ordered.—May 7th: Had a good night. No fit until 9 A.M., and then several fits in succession. The right side of the face and neck involved; head drawn to the shoulder of same side; angle of mouth depressed; and platysma working violently. Both arms involved; the right more than the left. Breathing rapid and thick. Could still be roused, but with increasing difficulty. Pupils dilated. Temperature 100°; pulse 100.—8th: Has had a fit every ten minutes throughout the night (statement of woman who sat up with him). He was comatose and breathing stertorously. Cold sweat was thick upon his brow. It was evident that he must die in a few hours unless relieved by operation. Dr. Somerville, to whose advice and assistance I am much indebted, met me in consultation, and we agreed to trephine. The man being placed under chloroform and trephined at the seat of injury, the dura mater bulging into the wound, there appeared some roughness, as though the internal table had broken inwards below the opening, and another circle of bone was removed, but nothing to account for the symptoms was discovered. The needle of a hypodermic syringe was thrust through the dura mater into the brain in several directions, without result. Finally, I passed a fine aspirating needle across to the right side, and thus explored the other hemisphere and dura mater without result. Ptosis and internal squint of the right eye appeared. I loosely sewed up the wound, introduced a moderate drainage-tube, and dressed with antiseptic tow, first well dusting the parts with iodoform. At night I found him breathing quietly. Temperature normal; pulse 100. No recurrence of fits.—9th: No more fits. Has slept throughout the night. Takes food well. Can be roused, but soon falls asleep again. All his movements coördinate. Pulse quiet. Temperature normal. Breathes quite easily; has not micturated. The ptosis and squint have disappeared.—10th: Got out of bed and voided urine naturally. Put out his tongue on being asked; spoke. Recognised his child; temperature normal; pulse quiet. Wound healed at upper part.—11th: Went downstairs to watercloset; returned to bed. Recognised his family; would not keep the bandage on his head. The progress of the case from this point was characterised by complete return of speech and muscular power, with control over sphincters. Unfortunately he was obstinate, would walk out, having removed the bandage; became irritable when opposed; wished to go to work on Sunday, and went to bed in his clothes. The wound broke down and suppurated. At this point I advised his removal to the workhouse infirmary. I hear from his wife that he has almost completely recovered (June 25th), the wound having healed. He is rather simple in manner, but quiet and self-possessed.

Remarks.—There is very little doubt that this man suffered from fracture through the anterior fossa by contre-coup, and that subsequent increasing hæmorrhage produced the severe symptoms of progressing compression from which he would have died. The hæmorrhage, I should say, was

Digitized by Google

located in the upper part of the ascending frontal convolution on the right side, and on the posterior end of the second frontal convolution of the same side. Probably the other side of the brain was also affected, and this will account for the cross symptoms the case presented. The friends stated to me that he fell on the right side of the head, but shaving the scalp disclosed the recent scar on the left side. It was the crossed condition which determined us to trephine at the seat of injury rather than at the point of physiological disturbance; and I was the more inclined to do this because I remembered to have seen cases of supposed occipital concussion productive of considerable mental confusion and irregular, almost choreic, movements. The relief afforded by the operation was too full to admit of doubt that it played the only part in the recovery, although nothing was found under the bone. The object of the operation did was manifestly to relieve tension, and thus the compression. In future, unless the apparent seat of injury corresponds with the symptoms produced, I shall trephine over the centres involved rather than the neighbourhood of the wound. Had I followed this physiological law instead of the old surgical axiom the result from an operative point of view would have been satisfactory, whereas now it is only interesting and negative.

Since writing the above I have seen the patient, who is quite well in every respect.

Macclesfield.

PUERPERAL FEVER: A POSSIBLE SOURCE OF CONTAGION.

By R. D. PEDLEY, F.R.C.S. ED. AND L.D.S.,

DENTAL SURGEON TO THE ROYAL HOSPITAL FOR SICK CHILDREN, SOUTH WALES; ASSISTANT DENTAL SURGEON TO THE NATIONAL DENTAL HOSPITAL.

Is it possible for a medical practitioner or a nurse whose mouth is in an unhealthy condition to be the means of developing in a patient puerperal fever or any of the local manifestations of septic poisoning, such as pelvic cellulitis or pelvic peritonitis? This question has many times presented itself since reading as a student a case mentioned by Dr. Playfair in vol. ii. of "The Science and Practice of Midwifery," of a medical man who, suffering from chronic caries, had to relinquish practice on account of the numerous deaths from puerperal fever among his patients. I have not been able to answer the above question in the affirmative, but I consider there is sufficient evidence to justify me in my doubts regarding the matter before those who are better qualified than myself to form a correct judgment. Some light may be thrown on the question of "Puerperal Contagion" by making mention of a case recently reported in the daily press of an inquest held on the body of a woman who had died from puerperal fever. The mother of the patient—an uncertified midwife—had been the means of spreading this terrible disease. Dr. Talbot, in evidence, stated that "he had attended her for a piece of dead bone in the mouth, and if she had been fingering it that might account for the outbreak." This, of course, is an extreme case. Probably the woman was suffering from syphilitic necrosis, and that her mouth was in a very bad condition, also that her acquaintance with antiseptics was practically *nil*. Most mouths are rendered foul by carious teeth, and there can be very little doubt that medical men and nurses are as liable to suffer from carious teeth as their patients, and find, as a rule, far less opportunity of seeking advice.

The condition I refer to is generally brought about as follows. A tooth is attacked by caries. If neglected this makes its way into the tooth until the pulp chamber is reached, and the nerve is exposed. After a variable amount of pain the nerve dies, and becomes putrid right up to the apex of the fang. A small amount of septic matter escapes through the apical foramen, and sets up an acute alveolar abscess. At this stage if the tooth is extracted the trouble is ended; but if the pus is let out beneath the lip, or makes its way through the thin alveolar plate, the swelling disappears after a day or two and a sinus remains from which matter is constantly discharged in small quantities. In dental language it becomes a chronic alveolar abscess. The tooth is practically a piece of dead bone; with this difference, that through its centre is a narrow channel in which rests the remains of a putrid nerve. It is quite common to find several teeth in a similar condition, sometimes cut down level with the gum, having received no further treatment than careful concealment by artificial teeth. Beyond the fact that an occasional swelling takes place in the alveolar plate, and a very disagreeable taste is present, the owner may go on for years with very little discomfort. Is it unreasonable to suppose that a very intelligent nurse (having several teeth such as we have described) may seek to relieve the pain of an aching stump by pressure of the fingers; and, not being aware of any danger, convey septic matter to the body of the patient in the ordinary discharge of her duties?

In May and September of 1886 two cases came under my care, in which I had reason to suspect this cause.

CASE 1.—Miss ——, a nurse, said she should have been before, but had been attending a case of puerperal fever. Her mouth was in an unwholesome condition. Front teeth good. Not a single molar sound; all the back teeth carious. Had two alveolar abscesses in connexion with upper bicuspid teeth on the right side, and one in connexion with a lower molar tooth on the left side.

CASE 2.—Dr. ——, suffering from an acute alveolar abscess over left lateral incisor tooth in the upper jaw. Face considerably swollen. Tooth had been sore for some time; he could scarcely bite anything with comfort. Teeth generally in a bad condition. Several stumps in the lower jaw on the right side and in the upper jaw on the left side. Had suffered for years; of late the stumps had given considerable trouble. Several abscess, from which pus oozed. Would have sought advice before, but just after tooth became troublesome had a puerperal fever case to attend to, and had been much worried. No reason to be assigned for puerperal fever; surroundings good and healthy. Good confinement.

That pus from an alveolar abscess is necessarily septic we cannot be sure; but there are three facts worthy of notice: 1. Pus from an alveolar abscess is often of foul odour. 2. As a consequence of alveolar abscess, necrosis of a portion of the jaw-bone is not at all uncommon. 3. There are cases recorded of patients who have died from pyæmia and septicæmia as the result of alveolar abscess, *vide* Tomes' "Dental Surgery," Salter's "Dental Pathology and Surgery."

It may be urged that the medical practitioner is constantly brought in contact with septic matter, and that the adoption of the necessary antiseptic precautions would exclude all possibility of such direct communication as I have suggested. This is quite likely; also think, if a source of danger is pointed out, the medical man may be trusted to do his best to avoid it. I would, however, be sure of the nurse, the patient's safety being dependent, as it is for the most part, on the nurse, and who, after the first few hours, has the wellbeing of the patient in her own hands. No medical man can be held responsible should the nurse fail to carry out his instructions; but he can, in most cases, ascertain beforehand that the nurse is not the subject of a malady, be it local or constitutional, which is likely to be a source of danger to his patient. In conclusion, I would offer this brief suggestion. It is desirable that midwives and nurses should be subjected to medical inspection before attending obstetric cases.

Railway Approach, London Bridge, S.E.

TRANSVERSE SEPTUM IN THE VAGINA TREATED BY OPERATION.

By CHAS. E. PRANCE, M.D., F.R.C.P.I.,

SURGEON PRESENTEE TO THE SOUTH DEVON AND EAST CORNWALL HOSPITAL.

IN THE LANCET of April 13th, Dr. C. J. Cullingworth reported on cases of transverse septum in the vagina which he had treated successfully. I was rather surprised to see in the bibliography appended to that paper how comparatively few cases had been recorded, and yet many such must occur, and it may be well to add to the record. It so happened that within one week in March last two such cases came under my care, and others, though not quite of the same kind, at various periods before. Of the two

lately occurring, in one—a young unmarried lady of twenty-five—I was actually consulted by her mother about her as suffering from menorrhagia and dysmenorrhœa; and yet, on digital examination, the septum (or diaphragm, which I think is a more accurate term) was so complete that I could with the finger detect no aperture in it, though doubtless there was some minute orifice, but so minute as to render the process of evacuation of the menstrual fluid a long-continued affair. I regret that in consequence of the removal of this patient with her family at that time from the town to a distance, I was unable to follow up the case for more careful investigation and further treatment.

The other case was that of a lady, aged thirty-two, who had been married nearly three years, and who was said to menstruate regularly and without any noticeable difficulty; there had been no pregnancy. The occasion of my being consulted was for general debility and various nervous symptoms and depression. In the absence of impregnation, and from her answers to questions suggested by that, the doubt occurred to my mind whether, notwithstanding the menstruation, there might not exist some mechanical obstacle to efficient intercourse. Digital examination revealed such an obstacle; one felt—as in the case mentioned before—only a sort of thimble-shaped cavity with a sufficiently wide opening, but apparently absolutely closed top; and per rectum I could feel higher up that the cervix and body of the uterus were of ordinary size. This being the case, I suggested an operation, and the surgical assistance of Mr. Connell Whipple, of this town, was called in. We together carefully examined her in a good light. The diaphragm was a fleshy one, of the same reddish colour as the parts around, with rather roughish surface, having some small fleshy papillary projections. We failed to detect any aperture, and the problem as to whether she really menstruated, or had some vicarious discharge which took its place, could only be solved by waiting until the next menstrual period. In rather less than three weeks we received notice that this had come on, when we met again. On examination, there was no menstrual fluid to be seen, and the only apparent change was that the thimble-cavity was much shallower and the top slightly bulged down. She was then directed to strain downwards; there was at once seen a small oozing of the menstrual fluid from the anterior part of the membrane, about one-third of an inch behind the urethral orifice—much as when one pricks with a pin an artist's bladder of oil paint,—the minute aperture was at the base of and hidden by one of the afore-mentioned papillæ. Mr. Whipple barely succeeded in passing a fine eye probe through it; an ordinary silver probe would not pass. This fine probe was then felt to move freely in the cavity of an ample vagina beyond, its point could also be felt by the finger per rectum, and the uterus above. The diagnosis being now clear, and operative interference justified, we waited six or seven days until the discharge had quite ceased. We then met again, and Mr. Whipple proceeded to operate. The patient being under methylene and placed in the lithotomy position, and the pinhole orifice having with a little difficulty been again found, it was dilated enough to allow the passage of a director, and on that a bistoury, with which the fleshy membrane was incised crucially; then the quarters were removed by means of scissors back to the level of the vaginal wall, so as to leave no projection. The hæmorrhage was trifling. The vagina was then well syringed out with a carbolised injection, which process was repeated daily thereafter by the nurse during healing. The vagina was now fully patent, would admit two fingers easily its whole length, and the os, cervix, and uterus felt normally developed. The patency was secured by the daily introduction, until healing was complete, of a good-sized finger-shaped wad of compressed cotton wool, smeared with vaseline, and the patient was kept in bed. In a few days she was quite well, and restored to her husband with a patent vagina, and I may add soon became pregnant. This is a different kind of case from that of an absolutely imperforate diaphragm, which I have also met with, and which is more common, and also other cases which I have encountered of circular dense hymen with a comparatively small central opening. The former reveals itself by entire absence of menstruation, and the suprapubic tumour is formed by gradual accumulation; but in such a case as the one detailed above, a fruitless married life may go on, uncomplained of obstruction, however strange it may seem, and menstruation go on regularly; so that there is no suspicion of the real state of malformation, until it may so happen that, the woman consulting a medical man, but not for that special purpose, circumstances suggesting suspicion may fortunately lead to an examination, and the state of affairs is revealed and safely remedied. One can hardly think of any malformation possibly involving momentous issues in family history, yet so readily set right, and with such satisfactory results. A caution, however, with regard to operative procedure in these cases suggests itself from my remembrance of another very different, though outwardly similar, kind of case, which occurred to me some years ago. I was consulted about a well-grown handsome young lady of marriageable age, who had never menstruated. On examination I found the same short, thimble-shaped cul-de-sac vagina, but on the most careful examination per rectum and above the pubes I could detect no uterus, and gave my opinion that there was none, and that no operation was advisable or feasible. She was afterwards taken by her parents to consult a specialist in London, who absolutely confirmed my opinion of the melancholy fact as one incapable of remedy.

Plymouth.

A CASE IN WHICH PERITONITIS WAS CAUSED BY VAGINAL SYRINGING AFTER TWO SUCCESSIVE CONFINEMENTS.

BY CHARLES SCOTT WATSON, M.D.

MRS. A. B——, a healthy primipara, was confined on Aug. 18th, 1886, after an easy and natural labour. Vaginal syringing night and morning with dilute Condy's fluid was ordered, and a Higginson's syringe was used for the purpose. All went well—pulse and temperature keeping below normal—for thirty-six hours—i.e., till 6 P.M. on the 19th, when, immediately after being syringed, the patient turned on her left side and was at once seized with severe pain in the left iliac fossa, soon spreading across the lower abdomen. Shortly afterwards she had a rigor, and the temperature rose to 103·4°, the pulse to 110. At my visit about 7 P.M. she was lying on her back in great distress, complaining of intense constant pain and of tenderness over the lower half of the abdomen. Both pain and tenderness were most severe in the left iliac region. Abdominal examination, as far as it could be carried out for the tenderness and resistance, disclosed nothing abnormal, and no vaginal examination was then made. About midnight the pain began to abate a little, but did not disappear till the 21st, when also the temperature fell to normal. On that date there was still abdominal tenderness, and on vaginal examination the uterus and vaginal roof were found to be tender, the uterus not freely movable, but not displaced. On the 22nd a dose of castor oil was given, apparently a mistake in the management of the case; for on the following day there was a gradual return of pain and tenderness (rather more diffused than in the first attack) and of fever, the temperature rising to 101° and the pulse to 100 on the evening of the 23rd. Under opium and poultices these symptoms again yielded, and on the 25th there was neither pain, tenderness, nor fever. From the 29th to the 31st the temperature ranged between 100° and 104°, in association with pain and tenderness in different areas of the breasts. On the latter date the uterus was well reduced in size, movable, not tender, the vagina everywhere soft and painless. Thereafter the patient did well. Her second confinement, again in every respect natural, took place on April 5th, 1888. Vaginal syringing (1 in 3000 sublimate) was again carried out twice daily with a Higginson's syringe. The patient made satisfactory progress up to the morning of the 17th, the highest temperature registered being 98·4°, the highest pulse 72. She got up on the eleventh day, and again on the twelfth. On the morning of the 17th—i.e., twelve days and a half after confinement—when syringing was being carried out the same accident again occurred. The patient was on her back, and had passed the vaginal tube herself without any pain or unusual feeling. After two syringefuls had been gently delivered, and while the fluid was returning clear, and apparently as freely as usual, she felt pain in the left iliac fossa. The pain rapidly increased, and after five or six syringefuls the patient felt very sick, and syringing was stopped. She then turned on her left side, when

10th.—A draught of air on face, back, or chest produces marked general spasm, but the pharynx and throat muscles do not seem to be chiefly involved. As far as could be ascertained, the spasm affected the trunk (erector, back [opisthotonos?]) and to kick up her legs from the knee, but perhaps a slight tendency for the limbs to cross. The whole part of the movement seemed almost purposive, but at each subsequent attack the same thing happened. There is occasional spasmodic contraction of the muscles acting on the left side of the mouth, drawing it strongly over to the left side. Temperature 101·6°; pulse 140. Chloroform was administered and the throat examined. It was generally red, and a few strings of *rapy* mucus could be seen. Half a pint of egg, milk, and brandy mixture was introduced into the stomach. She slept ten minutes after the anæsthetic, and was then very restless all the morning. There is a fairly constant dribble of watery saliva. She takes liquid nourishment with very little spasm. The temperature rose in the evening to 102°.

11th.—Patient slept a couple of hours after two doses consisting of five minims of tincture of opium and ten grains of chloral hydrate. On waking she complained of pain in the back of the head, and would not attempt to stop in bed. Legs seem weaker; speech indistinct, and she appears to have delusions. The face has an exceedingly wild, haggard look. There is some conjunctivitis, especially of the right eye, with muco-purulent discharge. Three drachms of succus comi given every two hours. During the day she continued to take nourishment in small quantities, with but little discomfort and no real pain or agony. She was again put under chloroform and fed by catheter in œsophagus, as before. She was not nearly so violent. In the afternoon she rambled incessantly, did not recognise her mother, rather rapidly lost strength in the latter part of the day, and the temperature rose to 103°. She lay in bed with a vacant stare on the face; eyes half closed. The legs and arms are occasionally jerked about; but there is no painful spasm, no screaming, and no paralysis. At 7 P.M. she became unconscious. Pulse over 200; respiration 36; and she remained practically in this state up to the time of her death, at 3.30 A.M. on the 12th. The temperature at 2 A.M. was 104·6°; pulse 160.

Necropsy eight hours after death.—Rigor mortis well marked. On opening the spinal canal there was found great engorgement of the vessels, especially at the sides of the canal, giving an almost uniform dark blue-black appearance. This appearance was especially well marked in the neck, where a very considerable quantity of very dark blood was present and escaped. A fair quantity of arachnoid fluid was present, but apparently not beyond the limits of health. No capillary congestion or any trace of inflammation of the membranes. Sections of the cord seemed extremely vascular, and the grey matter perhaps looked very pink, especially at the upper and lower extremities of the cord. The vessels in the substance of the cord were much distended, giving rise to the appearance of hæmorrhages. The vessels bled under observation, and the blood could in all cases be wiped off. The superior longitudinal sinus of the brain was filled with dark clot. Nothing noteworthy was seen in the naked eye in any part, perhaps the vessels in the fourth ventricle and the substance of the brain generally were a little more noticeable than usual. The other organs were healthy. The larynx was a little red and contained some tough mucus.

Microscopic examination of the brain and spinal cord, after careful hardening, revealed the following: In the cervical region of the cord the capillaries and bloodvessels were uniformly injected with blood. This was very evident in the grey matter, the posterior and anterior roots, and wherever the vascular supply was greatest. In the lower part of the medulla the lymphatic sheaths were swollen, and higher up, in the floor of the fourth ventricle, these were everywhere distended with leucocytes. The injection of the finer vessels was everywhere very manifest. In the cerebrum portions of the cortex in the frontal region were hardened, and, under the microscope, sections showed very well marked general congestion, the capillaries and blood-vessels being everywhere greatly distended with blood. No actual hæmorrhages were seen, and there was no obvious change in the nerve-cells or nerve-fibres generally.

Remarks by DR. ADAMS.—Several points are worth noting in this well-marked case of hydrophobia, to all of which, however, attention has previously been called. In the first place, the incubation period was rather short (five weeks)—within six weeks,—due doubtless to the youth of the patient, and the seat of the bite being on the face. The behaviour of the dog appears to have been very characteristic. It was a stray dog, was hiding in a dark cellar, and when disturbed showed the strong tendency to bite. The initial symptoms were also very characteristic. The pain typical and the course of the disease characteristic, thirstiness, malaise, loss of appetite, &c., were soon followed by the spasm stage, which later, although well marked, was never very distressing, the mental disturbance, which was very pronounced throughout, being a much more prominent symptom. The mania was intermittent, and subject to the sudden variations so characteristic of the disease, the child at one moment fighting and the next embracing the nurses in charge of her. As the case went on, the spasm almost entirely disappeared, concurrently with a loss of the deep reflexes and paralysis of the vagal centre, accompanied by hyperpyrexia and cardiac failure, terminated the case on the eighth day. With regard to the treatment adopted, inoculations were of course out of the question, the disease being fully developed when the patient came under observation, and with no beneficial effect. The administration of nourishment was difficult enough, life being prolonged to almost the maximum duration obtained in such cases. Owing to the throat, large doses of conium, and occasionally chloroform inhalations, certainly enabled her to have nourishment without discomfort, and during the whole course of the illness she appeared to have no suffering whatever. The great predominance of the mental disturbance over the other symptoms is not an uncommon variation in cases of hydrophobia; but whether from the fact of the vascular lesions affecting the cortex more than the medulla, or possibly from the treatment adopted in this case, it is difficult to make out. Mercury, which is said to have done good in one case, was powerless here, although the patient was rapidly salivated, and the case is another instance of how little can be done remedially in dealing with the established disease by means of drugs.

HOLBORN UNION WORKHOUSE, MITCHAM.

A CASE OF EXTENSIVE SUBCUTANEOUS EMPHYSEMA FOLLOWING THE RUPTURE OF A VOMICA; REMARKS.

(Under the care of Mr. OSCAR B. SHELSWELL.)

THIS case illustrates the occurrence of a somewhat rare complication of phthisis—the escape of air from a cavity of the lung into the subcutaneous tissue of the body, and its general diffusion. The account is full, and the pathology shown in the description of the post-mortem examination. Emphysema, as the result of a wound in the lung, is commonly met with in surgical practice: but as accompanying any form of disease of the air passages it hardly receive attention in works on medicine, a large number of which do not mention in the index subcutaneous emphysema. It has been described frequently as following excessive straining during parturition, also in cases of whooping-cough, and has been due to the perforation of an ulcer of the trachea or bronchi.

A. M——, aged sixty, was admitted into the infirmary on August 13th, 1889, suffering from phthisis. He stated that he was quite well till last April, when he coughed up half a pint of blood in two nights in "flakes," and has coughed more or less ever since, the phlegm at first being scanty, but gradually increasing in quantity. He has been losing flesh. There was no history of fractured rib or of any injury to the chest, and none of sudden pain after coughing at any time. Mr. W. A. Shelswell (who was at this time acting for Mr. Oscar Shelswell) states that the emphysema was first noticed about the right clavicle on August 22nd. It slowly progressed to the right shoulder, arm, hand, right side of face, right thigh, scrotum, leg, and ankle; the right eye was almost occluded. The left side was also affected, but much less than the right. On August 30th the emphysema was universal. There was no pain, but a feeling of tightness with his cough. Percussion note was hyper-resonant. Auscultation was impossible owing to the crepitations of the emphysema. He generally lay and slept on his left side. There was some dyspnœa; no pyrexia or albuminuria. He did not

Digitized by Google

notice his condition concerning the emphysema till it was pointed out to him. When Mr. Oscar Shelswell saw him again on the evening of Sept. 8th his condition was as follows. He was lying on his left side, and said he could not lie in any other position on account of his breathing freely more on the left side. Respiration was 36, temperature 101·6°, and pulse 120. His face was swollen, especially the right cheek, which was much distended. There was also distension of the tissues of the neck, thorax, abdomen, back, arms to hands, and legs to knees, and of the right leg a little below the knee. There was more on the right side, especially above the right clavicle, and about the upper right intercostal spaces than elsewhere. On pressure there was a dry crackling felt and heard. It was impossible to distinguish pulmonary sounds with the stethoscope on account of the displaced air causing a crepitating noise. There was hyper-resonance all over the chest. The sputum was abundant, thick, mucopurulent, and of a greenish colour. The tongue was moist and coated with white fur. He said he was in no pain at any time, but felt very weak. The swelling became much diminished by Sept. 12th. There was diarrhœa on the 12th and 13th. He gradually became weaker, but lingered till the twenty-first day from the first appearance of the emphysema, some of the swelling of which was apparently still considering his dangerous condition, which had been diagnosed as phthisis with ruptured vomica. He died quietly on the morning of the 15th, without any special increase of dyspnœa.

At the post-mortem examination, made twelve hours after death, the following condition was found: There was much emaciation, the body was quite warm, rigor mortis slightly marked. The connective tissue in many situations was much distended with air, principally on the right side of the body, the chief seats being at the upper part of the thorax on the right side and in the right supra-clavicular region. It existed also on each side of the neck and all over the thorax, abdomen, perinæum, scrotum, right thigh, right arm to the back of hand, and all over the back as far as the buttocks, to a slight extent in the left arm and less so in the left thigh. It was absent from the face (where it existed to a very great extent, causing a much bloated appearance), scalp, ears, legs, below the knees, and the left side of the thorax, abdomen, and back over the clavicle; parts a sensation was conveyed as of cotton wadding, and the sound resembled the same. The skin, loose and wrinkled in places, was dry and harsh. The air was easily displaced, producing a dry crackling sound and sensation, the indentation remaining. The right arm above the elbow measured in circumference three-quarters of an inch more than the left, owing to the air in the tissues. On the removal of the skin the subcutaneous tissue was seen to be very pale and silvery and streaked with very little fat; small vesicles of air were also seen, and their characteristic sound and feeling were produced by pressure. In the tissues outside the second right rib in the axillary line was a vesicle of air about the size of a small grape, but the vesicles generally were very much smaller than those described. The subcutaneous tissues on the left side of the thorax and neck contained a quantity of air, but very much less than on the right side. On carefully separating the right lung from the chest wall, a hole in the lung leading to a cavity was seen opening in the second intercostal space, and three inches from the middle of the sternum. Careful separation was effected by means of a probe, there being no intervening pleura apparent. The opening would admit the tip of the little finger; radiating inwards from its edge to about one-eighth of an inch was a very thin membrane. A similar but smaller opening in the lung was seen, corresponding to the first intercostal space; and a smaller one still between the two, this last being perhaps caused by the thin anterior wall of the cavity giving way a little on the separation from the chest wall. The right pulmonary and costal pleuræ were adherent and detached from the chest wall together, air outside the costal pleura rendering this easy, except at the upper lobe at the side and the back, where adhesions difficult to separate appeared to have been freely used, and in the removal the cavity was torn at its posterior part, showing the thinness of its wall. The combined pleuræ were thickened and of flesh-coloured tint, and numerous air vesicles were seen on the outside. The left pleura was free from adhesions except at the apex; on its anterior surface was a whitened streak of thickened pleura extending longitudinally in front of the upper lobe. There was no evidence of air either between the layers of the pleura or in the tissues immediately external on the left side. There was pus in the trachea and bronchi. The left lung was darkly mottled externally, greyish on section, frothy mucus, pus, and blood-stained fluid escaping copiously from the bronchi. Besides and communicating cavities were grey and portions of the lung sank in water. There was some emphysema of this lung at the edge of its base; its weight was 21b. 2oz. The right lung presented a cavity in its upper lobe about the size of a turkey's egg and its anterior wall, measuring 3 × 2 inches, was extremely thin, in several places being thinner than note paper; externally its anterior wall was rather dark, and presented none of the thickened flesh-coloured pleura seen over the rest of the lung. The cavity extended quite to the posterior part of the lobe; its contents consisted of greyish-yellow pus. A ridge of condensed pulmonary substance partially subdivided the cavity, extending transversely across the anterior wall, separating the upper from the lower openings above referred to, but not sufficiently to prevent the finger in the cavity passing from one to the other. On section numerous grey and yellow tubercles were seen, and several smaller cavities were present. Portions of this lung sank on section in water, and crepitated on the left lung. There was a considerable quantity of air in the anterior mediastinum, but none in the posterior. In the intestines were several ulcers. The other organs were wasted, but otherwise appeared healthy. There was much air in the tissues at the back of the abdomen outside the peritoneal cavity, also some in the tissues external to the pelvic peritoneum.

Remarks by Mr. OSCAR SHELSWELL.—This case seems of special interest on account of its rarity, a vomica seldom giving way as above described, owing to the fact that the wall is so generally composed of condensed pulmonary tissue, and having the pleura over it much thickened. On referring to the cases brought before the medical societies and other reports in THE LANCET for the last ten years, I find numerous references to subcutaneous emphysema resulting from injuries to the chest wall or other part of the air passages, from whooping-cough, and from parturition (said to occur once in two thousand cases), but no mention of a case similar to the above. None of the text-books do more than refer to it. Thus Quain's "Dictionary of Medicine and Practice of Medicine" is the following: "A very rare effect of excavation of the lungs is the production of subcutaneous emphysema. A case in point occurred in Guy's Hospital in 1852. The patient had been slowly sinking for weeks, and shortly before his death there was a slight crackling below the clavicle and at the root of the neck. Frantzel, in 'Ziemssen's Handbuch,' alludes to similar instances. As pneumothorax is not present, it must be assumed that ulceration extends through both layers of the pleura, the space between having been previously closed by adhesions." Frantzel, in "Ziemssen's Cyclopædia of the Practice of Medicine," in the article on Pneumothorax, writes: "This cutaneous emphysema is sometimes observed in caseous pneumonia without pneumothorax, in the case of a vomica reaching as far as the pleura pulmonalis, causing adhesions between this and the pleura costalis, and perforating both pleural folds at once."

Medical Societies.

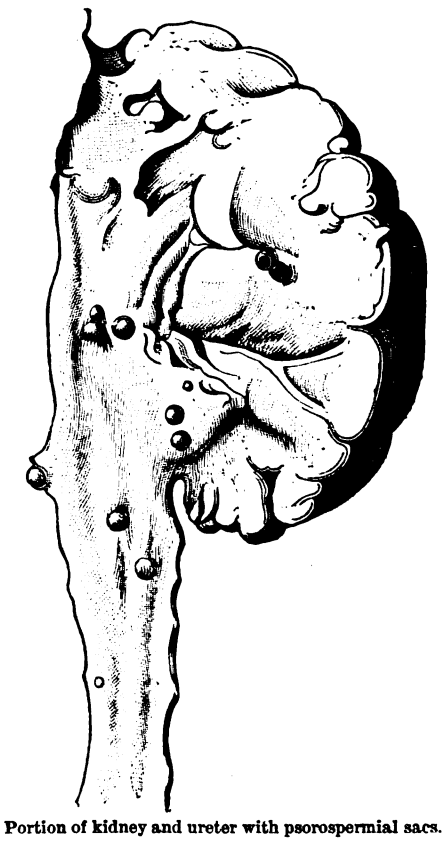
PATHOLOGICAL SOCIETY OF LONDON.

Cysts of Cerebellum.—Cerebellar Tumour.—Cancer of Breast following Eczema.—Paronychia.

AN ordinary meeting of this Society was held on Dec. 17th, Dr. Dickinson, President, in the chair.

DR. HADDEN exhibited a simple Serous Cyst involving the right lobe of the cerebellum. It was enclosed in the white matter, and there was no sign of growth, hydatid membrane, staining, or softening of the surrounding tissue. The cyst measured an inch and a half from side to side, and was filled with a clear serous fluid. The symptoms were those of cerebellar tumour. Two cases were reported in the Society's Transactions, one by Dr. Sharkey in vol. xxxii., and the other by Dr. Pye-Smith in vol. xxxvi. The exhibitor referred to another case which he had pub-

Digitized by Google



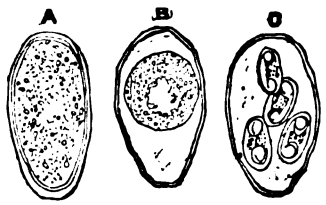
ished, and to one recently described by Dr. Mayor at the Bradford Medico-Chirurgical Society. The origin of these cysts was obscure; possibly they were due to the dilatation of lymph spaces. The explanation given by Mr. Althorp of Dr. Mayor's case was very doubtful. This gentleman suggested that the cyst might be a fœtal remnant, and alluded to the presence of a ventricle in the cerebellum of some birds.—Dr. GULLIVER showed an almost precisely similar case. The tumour was a central smooth-lined cyst in the right lobe of the cerebellum; it contained a fluid which was rather thick and colloidal in nature. There was no evidence of malignant disease.—Mr. BOWLBY asked if the cyst wall was examined microscopically in either case.—Dr. DICKINSON inquired into the condition of the lower extremities. In cases of one-sided cerebellar lesion loss of power but not of sensation in one or both lower extremities had been observed.—Dr. HALE WHITE referred to some investigations conducted by Dr. Savage and himself with regard to the pathology of holes in the brain. In two lunatics colloidal cysts were found in nearly all the organs of the body, and this was certainly against the congenital theory of their origin.—Dr. HADDEN, in reply, said that there was no paralysis and no staggering; he did not regard the cysts as of congenital origin. The cyst walls of these cases had not been microscoped, but in others examination had given negative results.

Dr. W. S. COLMAN showed a specimen of Simple Cyst of the Cerebellum, involving the middle lobe, and also excavating the white matter of the left lateral lobe. The symptoms had existed for two years: paroxysmal left occipital headache; reeling gait, with tendency to fall to left; occasional vertigo, with sensation of falling backwards; slowly progressive impairment of power in right arm and leg; prominence of both eyes, sluggish pupils, slight nystagmus, and double optic neuritis. Great improvement took place for a month or two, but death occurred suddenly from paralysis of respiration. On microscopic examination the wall of the cyst was found to be composed of layers of neuroglia. There was no trace of malignant disease, nor were there any other cysts in the cerebellum.

Mr. GILBERT BARLING showed a case of Alveolar Carcinoma of the Breast following Eczema (chronic papillary dermatitis) of the Nipple. The specimen was removed from a lady aged fifty-eight, who had suffered from the so-called eczema for six months. The nipple only was involved, and from it an indurated cord extended inwards on the equator of the breast for an inch and a half to a firm nodule the size of a horse-bean. The skin over the whole breast was movable and free from puckering, and the axillary glands were free from enlargement. Only the middle third of the breast was removed, including the skin over it and the pectoral fascia and muscle beneath. The patient remained well twenty months after the operation. A series of sections from the nipple through the indurated cord and the little tumour showed overgrowth of the rete mucosum with abundant small-celled infiltration. The lacteal ducts could be traced from the nipple to the growth, enlarged and distended with epithelium, whilst in places they were surrounded by small-celled growth. The small tumour was made up chiefly of alveolar carcinoma with traces here and there of duct carcinoma. He commented on the short time intervening between the origin of the eczema and the development of the carcinoma, and upon the general absence of squamous-celled carcinoma in these cases.—Mr. BOWLBY referred to Dr. Thin's observations, which had not been confirmed by subsequent observers. Dr. Thin held that the cancer was the primary lesion, and was the cause and not the result of the eczema. He had examined five cases, and in two there was eczema of the nipple without tumour, and this went to show that the disease of the nipple might precede the growth in the breast. In duct cancer of the breast he had not observed eczematous appearances. The cancer associated with eczema was usually spheroidal-celled carcinoma, and in most of the cases he had examined there was a distinct interposition of normal breast tissue between the cancer and the diseased nipple. The patients had remained well after removal of the nipple when that was alone diseased, and also in some cases after the removal of the cancerous breast. One case was well for five years and another for four years afterwards. In one case, after removal of a diseased breast eczema developed in the opposite nipple; this was also removed, but the patient died of a recurrence in the median line. In all the cases of diseased nipple the breasts showed retrogressive changes because the patients had passed middle life.—Mr. R. W. PARKER had examined one case of eczema of the nipple unassociated with tumour, but there was abundant evidence of abnormality of the breast tissue. He laid open the ducts and found that the disease extended directly from the nipple to the breast. He inquired if in Mr. Barling's case the nipple ducts were examined. He agreed with Dr. Thin that the eczema was due to irritation caused by fluid secreted by the diseased breast.—Mr. BARLING, in reply, said that the nipple ducts were not healthy, for they were distended, and there was a small-celled infiltration round them. In duct cancer a slight discharge was usually present, and the woman could squeeze from the breasts a fluid something like milk, though not lactating. He found hyaline material round the ducts, but no fresh development of elastic tissue such as Dr. Thin had described.

Mr. BLAND SUTTON described a kidney and ureter which had been preserved in the museum of the Middlesex Hospital for many years as an example of mucous cysts in the ureter. The characters of the supposed cysts strongly suggested the notion that they were of a parasitic nature.

FIG. 1.



Portion of kidney and ureter with psorospermial sacs.

Recently portions of the ureter containing the small rounded bodies were prepared by the celluloidin process, and found to contain the so-called psorospermial bodies. These were oval-shaped capsule 0·037 minim in length and 0·02 minim in diameter, and identical in microscopical characters with the coccidium oviforme, the parasite which was the cause of the destructive liver disease of the rabbit. In the specimen exhibited (Fig. 1) the psorosperm sacs were immediately beneath the mucous membrane of the ureter, and did not invade the muscular coat. No saccules or coccidia could be detected in the renal tissue. The relation of the coccidia to the ureters was investigated with care, because Leuckart, the greatest living authority on this disease, stated that in the bile ducts of the rabbit the coccidia developed in the epithelial cells. This was certainly not the case in the ureter, and required confirmation in the case of the bile ducts. The subject had attracted but little attention in this country. The Transactions contained only two specimens: one by Dr. Hadden, published under the misleading title of "Disseminated Sarcoma"; the other in the Kidney, by Mr. Eve, last

Digitized by Google

year. It was curious that the disease was not more frequent in man, for it was extremely common in rabbits: for instance, quite recently 500 rabbits were imported from Holland for examination purposes; of these, 60 to 66 per cent. had well-marked psorospermial disease of the liver. It was comforting to reflect that eating rabbits thus affected would not infect the eater, and that man and rabbits probably got coccidia from the same source, whatever that might be. Our knowledge of the life-history of this parasite amounted to this: In the young coccidium the granular protoplasm entirely filled the capsule; later it became concentrated in the middle, as shown in Fig. 2 (A and B). This change was but merely accidental or due to methods of preparation, as the stage A stained with

FIG. 2.

Coccidium oviforme. A, B, Stages found in rabbits and man. C, Stage occurs outside the body. (After Leuckart.)

methyl violet, but stage B stained best with fuchsin. It seemed that, however long the parasite remained in the body, it underwent no further change. After leaving the host the protoplasm gradually gave rise to four spores, as at C. No one, so far as he knew, had seen the stage C whilst the parasite had been lodged in the tissues of its host. The history and development of the coccidia in man and rabbits, as well as the symptoms to which they gave rise, were identical. Unfortunately, the source of infection and the condition of the coccidium, when introduced into men and rabbits, were unfortunately unknown. Darier had recently attempted to show that some skin affections, such as molluscum contagiosum, chronic eczema of the nipple, and the like, were cases of psorospermia. The evidence, however, was far from being conclusive.

Mr. SILCOCK related a case of Parasiticism by Psorospermia. The patient, a woman aged fifty-three, was admitted to St. Mary's Hospital seven days before death. She was thought to be possibly suffering from typhoid fever. The illness dated from a chill taken seven weeks before death. The symptoms consisted in pains in the limbs, nausea, and occasional sickness, tenderness over the liver and spleen, fever of remittent type, the temperature reaching 103°, and slight diarrhœa. The urine was albuminous; the splenic and liver dulness increased; the tongue coated with brown fur, becoming dry; the breath foul. Death resulted from cardiac failure. The necropsy was made eighteen hours after death in the middle of July. The liver was much enlarged, weighing eighty-three ounces. In its substance were a number of aggregations of caseous foci, for the most part near the surface, there being generally a well-marked red ring of congestion or capillary hæmorrhage around each caseous area. The spleen was enlarged, weighing sixteen ounces, and exhibited similar caseous foci varying in size from a pin's head to that of a pea, arranged in aggregations, and with a red inflammatory zone around each nodule. In the ileum were found six papule-like elevations, with red bases and circumferential inflammatory zone; also in the large intestine, as well as in the ileum, were red patches of infected mucous membrane, from one to three inches square. A small pneumonic area existed in the anterior border of the left lung; the other organs and tissues presented no noteworthy change, except those associated with fever. The naked-eye post-mortem appearances to a certain extent resembled those of tuberculosis, but different in the character, situation, and limited generalisation of the lesions. On examination of the caseous nodules, coccidia were found which corresponded in every respect with those described by Leuckart. The psorospermia did not appear to develop within the body, a fact noticed by this author; but they were obtained by keeping the coccidia in water and at an equable temperature in a warm room or incubator. It was a very remarkable fact that the development of the psorospermia went on in a weak solution of bichromate of potassium such as is used for hardening purposes. The resistance and toughness of the coccidium capsule probably explained this occurrence, as also the difficulty experienced in getting the organisms to stain with any of the reagents in ordinary use. The histological characters of the liver and splenic lesions were admirably given by Leuckart, and to his description there was at present nothing to add; that the coccidia were present in the bile ducts, and that their topographical distribution was regulated by the latter, were also obvious from an inspection of the specimens; but it was noteworthy that the only intestinal lesions found were far away from the duodenum. Their presence in the spleen could only be accounted for on the supposition that they had been carried there in the blood stream. This was the first case of the kind which, so far as he knew, had come under his notice, but from the marked *primâ-facie* resemblance of the disease to tuberculosis he could not doubt that it was much more common than was generally imagined. Mr. Silcock was very much indebted to Mr. Rogers, of St. Mary's Hospital, for the excellent specimens which were before the Society, and for the working out of the case generally.

Dr. DELÉPINE said that the presence of psorospermia in the liver of rabbits was a fact of such common occurrence that it hardly attracted the notice of the histologist, notwithstanding the use which was made of rabbits for experimental purposes. He had had lately to examine a large number of rabbits for special purposes, and, wishing to avoid as much as possible serious errors, he had made a point to note carefully the amount of psorospermic nodules found in each case. This was done chiefly with the view of discovering whether the diseased livers would react to various agents as well as those which were little or not diseased, and whether the presence of psorospermia diminished in any marked degree the vitality—a serious pathological state as to render them unfit for the carrying out of comparative experiments. Out of fifty rabbits of which the necropsy had been made during the last few months, only four were found apparently, and two certainly, free from the lesions produced by psorospermia. Thus 92 per cent. were certainly affected, and possibly 96. Some of these rabbits were obtained in London; the greater number was, however, of Swiss origin, and obtained from various farms. (Psorospermia were apparently more abundant in Swiss than in English rabbits.) All these animals were young, but varied considerably in size, the smallest weighing 688 grammes, the largest 1675 grammes. He had the occasion to examine in Geneva a large litter of young rabbits, and found that the animals were of different sizes. But, contrary to his expectations, he found that some of the small rabbits had very few psorospermia in their liver, whilst some large individuals were infested to a considerable extent. However, these animals having all been submitted at the same time to a rather long preliminary fast, two of them died, and these were very small. In one of them the liver was almost entirely replaced by psorospermial nodules. In the other the gall-bladder was distended with a clot, resulting from hæmorrhage caused by ulceration of the roof of the gall-bladder; the rest of the organ was comparatively free from lesions. Of those that remained, one other got very ill, and psorospermia were also extremely abundant. But of the six that remained, it was found on opening the body that the largest, and the one that had been the most active, was also the one in which psorospermia were most abundant. From this it would seem that in a very young rabbit psorospermia may multiply to such an extent as to be a serious dange. to the life of the animal, but that after the first few months the presence of even a large number of psorospermia did not interfere much with the nutrition of the animal. He continued the investigation on another line. He weighed carefully the whole body and the liver of all the rabbits which he had to dissect; 32 rabbits were thus examined. Out of that number, 2 were found free from psorsopermia; in 9 a psorospermium could be found here and there in the liver; in 8 the parasites were scattered all through the substance; in 10 the psorospermia were abundant; in 3 they were so abundant that it was almost impossible to find a single cubic centimetre of liver tissue free from them. The average weight of the animals belonging to these various groups was as follows:—Psorospermia: absent or nearly absent, 979 grammes; pretty abundant, 871 grammes; abundant, 1010 grammes; very abundant, 790 grammes. Thus it appeared that so long as the psorospermia were not very

Digitized by Google

abundant the nutrition of the body was not much interfered with (it must be remembered that the three rabbits representing the last group were all very young). The average weight of the liver in these various groups gave more interesting results. In order to render that weight comparable, the average weight, having been found, had been reduced to what it would be in rabbits weighing 1000 grammes in each case. The liver would, when so reduced, weigh: In animals in which the psorosperms are few or absent, 29 grammes; pretty abundant, 35 grammes; abundant, 33 grammes; extremely abundant, 35 grammes. Thus it appears that although the general nutrition was not much affected, yet the liver was distinctly diseased, as its weight showed. The nature of the changes found next attracted his attention, and he found, like previous observers, that the parasites must creep in by the bile ducts. Sections showed that the cells contained all of very large highly refracting bodies, escaped from their envelope. The granules now probably penetrated into the protoplasma of the epithelial cells, and in this way a large number of these cells was invaded at the same time. The small mass then developed into a larger protoplasmic mass, which at first was nucleated and nucleolated, then very granular, and finally escaped from the cell: it might become encapsuled or not. In some of these cells a long coiled filament was produced, the nature of which he could not determine. It might be the pseudo-filaria of Van Beneden, in which case there could remain no doubt as to the relation between gregarinæ and psorosperms. The lesions produced were at first limited to the infected epithelium, remarkably fine specimens of papilliferous cysts being thus produced; then the connective tissue was involved, and a certain proliferation of connective tissue took place. Ultimately a kind of biliary cirrhosis was produced.—Dr. HADDEN referred to the clinical history and pathology of his case, which had been before described.[1] The psorosperms were found in the heart, pericardium, pleura, peritoneum, liver, and spleen, being subscapular in the latter organs.—Mr. TARGETT had found one specimen in the museum at Guy's. It was a kidney from a young man aged thirty, who had been under Dr. Richard Bright's care fifty-three years ago; in the pelvis and ureter were found small cysts. Five varieties of psorosperms had been described, and probably only the smaller species affected man.—Mr. SPENCER related his experience at the Brown Institution. When the parasites were numerous they affected the health of the animal. He had found them in rats, mice, dogs, and cats; he had not discovered them in the sea-fish. They acted as irritants, and caused epithelial proliferation and connective tissue formation.—Mr. REVNOLDS had found one instance in the dissecting room at Middlesex Hospital, and referred to a fatal epidemic of the disease amongst rabbits.—Dr. PAYNE had not seen this disease in the human being. Bollinger of Munich had described a similar parasite in human skin as the cause of molluscum contagiosum. He himself did not know how to distinguish psorosperms when he saw them; if the structureless masses of colloid found were stated to be animals, it might be difficult to contradict, but he would like some better evidence. He asked if any parasite of definite structure had been found in the skin.—Mr. SHATTOCK asked for a description of the intestinal lesions in the cases. He thought the parasites might not have passed up the liver along the bile ducts, but might have escaped from the intestine and subsequently have entered the ducts.—Mr. W. L. SIBLEY gave almost a case in a carp which was erroneously described as one of multiple sarcoma. In molluscum contagiosum he had seen appearances like those described in the papers. He pointed out that these structures shrank rapidly in hardening agents.—Dr. PRINGLE had seen the specimens of Darier and Wickham, which appeared to him convincing, but inoculation experiments had not at present been performed.—Mr. SUTTON, in reply, alluded to Cohnheim's observation that psorosperms of the floor of the fourth ventricle failed to produce diabetes in rabbits whose livers were infested with psorosperms. Investigations into this disease in animals should be cautiously made, for in the monkey he had found what he at first regarded as psorosperms were really cases of sclerosis.—Dr. HADDEN, in reply, thought that the finding of these bodies in the spleen proved that they entered by the blood; besides which the liver many were found outside the ducts. The intestinal lesions in his case were limited to the lower ileum and the first part of the colon.—Dr. DELEPINE, in reply, said they produced in the rabbit a disease like biliary cirrhosis. The proliferation of the epithelium under the stimulus of their presence could not be doubted. Blake, previously to Müller, had described these structures; various continental authorities had shown that the organism was one of the protozoa, though possibly an immature form of some higher animal.

[1] Trans. Path. Soc., vol. xxxix.

The following card specimens were shown:—

Dr. HADDEN: Cast of Œsophagus expelled during life.

Mr. SPENCER: (1) Cystic Kidney from a horse; (2) Sebaceous Horn on a Mouse.

Mr. JACKSON: Subdural Hæmatoma.

CLINICAL SOCIETY OF LONDON.

Acromegaly.—Charcot's Disease of Shoulder-joint with Suppuration.—Inflamed Nerves of Leg.—Tumour of Frontal Bone.—Rheumatic Nodules.—Thyroid Adenomata.—Diffuse Aneurysm of Calf.

AN ordinary meeting of this Society was held on Dec. 13th, Mr. Christopher Heath being in the chair.

Mr. A. Q. SILCOCK brought forward a case of Acromegaly in a female aged fifty-three. Her fingers began to grow larger six years ago, her features had increased in size, and the lower jaw was massive and projecting. The cartilages of the nose and the tongue were much bigger than normal. The feet were likewise enlarged, but not to such a degree as the hands.

Cases of acromegaly were also shown by Dr. PEAKE FLEMING and Mr. K. CAMPBELL which illustrated various points in the clinical history of the affection.

Mr. CHARTERS SYMONDS introduced two cases from which he had removed thyroid cysts: one of the patients showed ocular sympathetic paralysis.

Mr. SPENCER showed a case of Charcot's Disease of the Shoulder-joint which was at first a simple serous effusion, but later underwent suppuration.

Mr. J. H. MORGAN showed an infant with a condition of the leg which he described as Inflamed Nævus associated with Multiple Subcutaneous Hæmorrhages.

Mr. MORGAN also exhibited a boy aged eleven who had a Tumour of the Frontal Bone, which commenced five years ago, and had gradually attained to the middle of the forehead. He suffered from frequent headache.

Dr. ANGEL MONEY showed a boy aged ten, who had Symmetrical Indurations in the spaces in front of each elbow. Mitral disease, erythema multiforme, erythema nodosum, motor instability, and rheumatic subcutaneous nodules showed that the girl was rheumatic. Dr. Money thought that the indurations were bony, but whether part exostoses, or exostoses *plus* periostitis, or periostitis simply, or whether originating in the bursa beneath the bicipital tendon, he could not say. The mother declared that the hardenings varied in size; schlags and shootings were experienced both in the affected parts and away from them, in harmony with changes of weather.

Mr. CHARTERS SYMONDS read the notes of eight cases of Cysts and Adenomata of the Thyroid treated by extirpation of the growth, six in women and two in men; one of these died. The ages ranged from twenty-two to sixty-three. He sketched the other methods of treatment by injection and incision, and the method used by Professor Hahn, who ligatured masses of fascia and gland as he removed the cyst. In one of the cases recorded the entire thyroid was removed with a tumour that lay partly beneath the sternum. The lobes were empty, and Mr. Symonds regretted that he had removed them. The operation was undertaken early in 1883, before the cachexia following removal of the whole gland was generally known, and the wide oozing surface left after removal of the growth seemed to promise hæmorrhage. In the next case there was a solid tumour behind the right lobe, causing dysphagia so complete that the patient had to be fed with a tube. The lobe and tumour were removed by an incision to one side of the tumour and over the growth. Hæmorrhage was considerable, maintaining pressure, and this was two to the incision being made. On dissecting this tumour, it was found to be encapsuled and to be situated behind, and might easily have been enucleated. Consequently, in subsequent operations Mr. Symonds decided to first search for the capsule and then enucleate. In four subsequent cases this was done, and the growths, in one case solid, in the others partly cystic, were

removed without the loss of any blood, and with great facility. As a rule, at most these small vessels required ligature. In one the lobe had to be raised up before the cyst could be reached. In the remaining case the lobe was removed because it appeared to be blended with the cyst; it turned out subsequently not to be the case. All the patients recovered with primary union, and most required but one dressing subsequently to that made at the operation. Then the method employed was detailed, and may be thus summarised: To make in every case, no matter where the tumour be situated, a median incision; it gave more room and left less scar, and when the deep fascia was opened the largest growth could be brought to the median line. To expose certainly and definitely the cyst or adenoma—i.e., its fibrous wall—and then to dissect off the gland. If the wall be followed closely no bleeding or trouble was encountered. If the white glistening wall of a solid tumour or the bluish wall of a cystic one was not seen at once, then the edge of the gland must be sought and raised up till the capsule was seen. If a dissection were commenced outside this, severe bleeding would be encountered. In the case of a cyst, Mr. Symonds advocated opening it early, after sufficient of the wall had been exposed to secure with forceps, and dissecting back the thyroid just as in ovariotomy. By this means the operation could be performed through a smaller opening, and the resulting scar was slight. The similarity in anatomy between these cysts and adenomata and those of the breast was pointed out, to explain why it was that the growths could so easily be turned out. All the cysts contained in the wall a variable amount of gelatinous glandular material, which showed the usual veins lined by cortical or columnar epithelium, and this structure was exactly the same as in the solid forms. As to diagnosis, it was pointed out that the cases suitable for operation were those in which the growth was localised, well defined, and limited to one side. In no case were there two tumours, though multiplicity was not considered to negative operation, there being no reason why two or more localised encapsuled growths should not be extirpated at the same time. It was impossible to decide between cystic and solid forms without exploration. It was held that excision gave more speedy recovery, and was freer from danger than any other method, while the small scar resulting from injection seemed to the author to be counterbalanced by the prolonged treatment and the often severe hectic that followed. Mr. Symonds also pointed out the necessity of the strictest antiseptic precautions in these cases. He had employed the spray except in four cases, where the wound was kept full of sublimate solution. But more particularly he called attention to the necessity of surrounding the neighbourhood of the wound with towels wrung out of lotion, and of operating with the arms of the assistant as well as the surgeon bare, and of wearing a clean linen apron or a towel pinned over the waistcoat from the neck downwards. These subsidiary precautions he considered of far more importance than the spray. He further added that in all the cases except one there were symptoms sufficiently important to demand operation. The exception was that of a lady who requested that the growth might be removed. He deprecated operation where symptoms were absent. Two patients were exhibited: one, from whom an adeno-cystoma measuring three inches by two inches was removed through an incision one inch and a half long, presented only a very small scar. The other still exhibited the ocular symptoms of sympathetic paralysis, which had antedated the operation performed nearly three years ago.—Mr. HEATH said he had treated a fair number of cases by injection, and though some of them had had afterwards a high temperature, he had not seen that great constitutional disturbance which Mr. Symonds had spoken of.—Mr. SILCOCK showed a Cyst of the Thyroid which he had recently removed. He was unable to delimit the cyst from the gland substance; he made, therefore, a median incision and removed the whole lobe without the least hæmorrhage; he dissected it from the middle line, tying the vessels as he came to them. In one case after injection he had seen diffuse suppuration of the neck, and an abscess in the anterior mediastinum.—Mr. SPENCER inquired what happened to the rest of the gland after division of the isthmus. In one case where he had done this the two lateral lobes had since slightly shrunken.—Mr. PARKER had observed a considerable diminution in the size of the thyroid after division of the isthmus.—Mr. BATTLE said that Mr. Sydney Jones divided the isthmus for dyspnœa, and he did it to obtain atrophy of the gland afterwards. He asked Mr. Symonds whether he had come across cases in which there was communication of large vessels with the interior of the cyst. In one case he had to pack a cyst with gauze to arrest hæmorrhage.—Mr. BERRY said the common course was that when one lobe was removed the other diminished at first in size, and then afterwards re-enlarged. The hæmorrhage came mainly from the vessels along the upper and lower borders of the isthmus. Socin of Basle had successfully enucleated forty-seven tumours from the gland, and his results had been published in a small pamphlet by Dr. Keser.—Mr. GODLEE said that for the removal of small parts of the thyroid body he made a small incision and scooped out the contents of the gland. The only hæmorrhage came from the capsular veins, the pulp not bleeding at all. He had known of disasters from the injection of perchloride of iron.—Mr. SYMONDS, in reply, said that he had not encountered any hæmorrhagic cysts. If one kept free of the capsule, there would be but little bleeding.

Mr. BATTLE then related a case of Diffuse Aneurysm of the Calf of the Leg which simulated Abscess. The patient was a labourer aged twenty-eight, who was admitted into St. Thomas's Hospital in December, 1887. The history was that five weeks before admission the man was descending a ladder when his foot slipped off the last rung. Next day the left leg was painful, and there was slight swelling of the calf. He consulted a medical man, who gave him some liniment. He was then able to get about and do his work for a few days, but at the end of a fortnight the swelling began to increase rapidly, and the pain became very acute, preventing rest. The family and previous history of the patient were good. The leg was swollen, painful, and tender, and measured one-third more than the right. There were fluctuation and œdema five inches above the ankle-joint; the swelling did not pulsate, and there was no pulsation in the arteries below. The temperature was 102·8°, with a furred tongue and full pulse. An antiseptic incision revealed a cavity containing blood, and at the operation next day an opening was found in the posterior tibial artery just below the origin of the anterior tibial. As a small branch artery from the popliteal to the inner head of the gastrocnemius had been divided earlier close to its origin, and the opening in the posterior tibial was so close to the bifurcation, it was necessary to ligature above and below those points respectively, and also the anterior tibial at its commencement, after which the artery between the ligatures was dissected out and removed. The opening from which the blood had escaped was situated on the posterior aspect of the vessel, the margin of which showed five granulations, but no atheromatous change, nor was any formed in the part removed. There was no sac other than that formed by the condensed tissues, the surface of which was shreddy, whilst the interosseous membrane had lost its firmness, and could be made to bulge forwards under slight pressure, restoring the rounded aspect of the anterior part of the limb, which had been so marked when the patient was admitted. Antiseptic dressing was applied and three drainage-tubes inserted, the wound, which was about eight inches long, being closed with interrupted sutures, and the limb enveloped in cotton wool and again placed in the splint. Further examination of the patient showed no evidence of disease of the heart, arteries, kidneys, or any of the internal organs. The foot was at first cold and waxy, but the circulation gradually improved, notwithstanding the fact that many sloughs came away. Later, a sharp attack of erysipelas, with suppuration in the knee-joint, retarded the healing of the wound, and before ultimate cicatrisation occurred the newly formed scar tissue broke down on several occasions. Mr. Battle then alluded to the difficulty in diagnosing some cases in which blood had been effused into the tissues of a limb after subcutaneous rupture of an artery, and added as an appendix a short record of cases of a similar kind. Guthrie had a patient under his care who had a rapid swelling of the calf of the leg, with a history of a swollen pulsating swelling preceding it. There had been a rupture of a posterior tibial aneurysm. In the *British Medical Journal* for 1878 was recorded a case of aneurysm of the posterior tibial, resulting from a wound of the calf of the leg seven months previously. It was proposed to try Esmarch's bandage, but the result was not given. Gross recorded (*Philadelphia Medical Times*, vol. ii., p. 374, 1871) a case of aneurysm of the posterior tibial artery, which formed a

Digitized by Google

pulsating tumour in the middle of the calf. There was a well-marked bruit. The swelling dated from six months before, and was noticed directly after the patient, a man of thirty-four, had jumped a fence. He felt something give way at the time. There was a curious history in this case. It was said that nineteen years earlier he had received a wound in the calf of the leg, whilst bathing, from the spine of a stingaree fish (Trachinus draco), and Gross inclined to the opinion that the aneurysm was the result of the rupture of a cicatrix of the artery which formed then. He ligatured the posterior tibial through an incision four inches in length, and the patient recovered. A postman, under the care of Spence, had received a wound from a knife in the upper and inner part of the left leg, five weeks before admission (*Med. Times and Gaz.*, 1872). That surgeon made an incision about eight inches in length through the gastrocnemius and soleus muscles, and evacuated pus and clot. The posterior tibial had been injured close to the popliteal, and also one of the venæ comites. A ligature was applied above and below the wound in both artery and vein, and another upon the anterior tibial, just below the bifurcation of the popliteal. These ligatures were left hanging out, the part covered with cotton wool and slightly elevated; the ligature separated in eight days, and the man recovered.—The PRESIDENT referred to the great difficulty in diagnosing these cases, and mentioned an instance which he recently saw which was hard to tell from tumour.—Mr. BERRY referred to the case of a boy aged twelve from whom he had removed a sarcomatous growth from the upper end of the fibula as large as an egg. He was obliged to tie the anterior and posterior tibial and the peroneal arteries. It was seven days since the operation, but no gangrene had at present supervened.—Mr. BATTLE, in reply, said he was surprised that his own case did not proceed to gangrene.

OPHTHALMOLOGICAL SOCIETY.

Hereditary Tendency to Cataract in early Childhood.—Operative Treatment of Cicatricial Ectropion.—Operative Treatment of Symblepharon.—Primary Tuberculosis of Iris.—Tea-leaf Conjunctivitis.

AN ordinary meeting of the above Society was held on Dec. 12th, the President, Dr. J. Hughlings Jackson, in the chair.

Dr. TATHAM THOMPSON (Cardiff) gave a description of well-marked Heredity of Cataract through four generations. The cataract developed when the individuals were from three to five years of age, and in all the cases quoted, except one, affected both eyes. There was at first a finely granular opacity of the entire lens, which rapidly increased in density till vision was reduced to mere light-perception. The cataracts were much harder than those of the ordinary congenital or the lamellar type. One peculiar feature was that the tendency was transmitted in two generations only through the male line, thus differing from the somewhat similar cases recorded by Mr. Berry in the *Ophthalmic Review* for January, 1888, but agreeing with the observations of Hosch and others. The heredity was more marked in the early childbearing period; this was also noted by Mr. Berry in his patients. In reply to questions by the President, Mr. Rockliffe, Mr. Gunn, and Mr. S. J. Taylor, Dr. Thompson said that his patients were in all other respects healthy, and there was no evidence of further disease of the eyes. No information was obtainable enabling him to explain the curious inheritance. No consanguinity existed in the parents of the affected children.

Mr. TWEEDY described a method of operative treatment for Cicatricial Ectropion of the Lower Eyelid, by which he had obtained very satisfactory results. He showed a patient upon whom he had operated, and a drawing of the same patient previously to operation. He made a doubly curved incision from the outer canthus downwards and outwards over the malar prominence, and a second parallel incision about six to eight millimetres to its inner side, carried through the whole thickness of the everted lid. The flap thus formed was dissected up, remaining attached only at the lower end. He then made a single straight incision obliquely across the cicatrix, nearly parallel to the lid margin; the outer end of this reached to the innermost of the two curved incisions. The lid and adjoining skin were then separated from the subjacent tissues. This allowed the cut surfaces at the sides of the flap to be brought closely together and united by sutures, and the eversion of the lid was thus corrected. The gap left by the drawing up of the lower lid was filled by the flap previously made, which was turned inwards towards the nose, and secured in position by a few stitches.—Mr. MACKINLAY asked if the depressed cicatrix, usual in such cases, was filled up by this method of operating. In the case shown there still remained a rather deep depression.—Mr. SPENCER WATSON fully appreciated the ingenuity of Mr. Tweedy's method, but thought that for most cases a simpler operation would suffice.—Mr. TWEEDY, in reply, said that the operation he had described was designed for the cure of the ectropion. In the particular case exhibited there was a large osteophytic mass at the lower margin of the orbit, covered by a very thin cicatrix, and that little could be done to remedy the depression at the site of the scar.

Mr. TWEEDY also gave a description of a procedure he had adopted in cases of extensive Symblepharon following Burns. It was most suitable for those instances in which there was a prolongation of the cicatrix into the cornea. His plan was to freely separate the lid from the cornea and globe, making a sulcus rather deeper than that of the normal conjunctiva; then, having attached two or three fine doubled silk threads to what had been the uppermost margin of the symblepharon, to pass these by means of curved needles through the lid from the bottom of the sulcus, bringing them out on the skin surface as near the lower orbital margin as possible. These threads were then tied over a piece of drainage-tube, and allowed to remain in position for four or five days. By this means the cutaneous surface of the corneal portion of the symblepharon was folded inwards and became the lining membrane of the lid. The patient should be kept under observation during the process of repair, so that any adhesions which formed between the lid and the globe could be broken down. If the lower lid were much incurved by the folding of the flap, its position could be restored by buttonholing the flap near the margin of the lid.

Dr. HILL GRIFFITH related particulars and showed specimens and drawings from a case of Tubercle of Iris, which occurred in a female child aged seven months. The eye had been affected for one month, and the child subject for three months to attacks of bronchitis and diarrhœa; there was an enlarged gland in the neck on the same side, but there were no other physical signs of tubercle. The parents were healthy, and there was no family history of phthisis. A yellowish nodule grew from the periphery of the iris of the right eye, and numerous millet-seed bodies from its surface; the pupil was closed, but there was no acute inflammation. The nodule grew rapidly, and the smaller deposits multiplied day by day. The eye was enucleated after three weeks' treatment. The disease was found to be confined to the iris and ciliary body. The new growth exhibited the histological characters of tubercle; but Professor Dreschfeld failed to detect the bacillus tuberculosis. In thirty-two recorded cases in which microscopic and other tests left no doubt as to the tubercular nature of the disease, one eye only was affected in twenty-nine; the average age of the patients was twelve, youngest four months, oldest fifty-one years. In ten cases bacilli were searched for, but only found in four; in one of the remaining six cases, however the inoculation test was successful. Three cases in which no operation was undertaken terminated fatally from tuberculosis. Of the twenty-seven cases in which enucleation was performed, two died with brain symptoms, but several others showed signs of tubercle subsequently to the operation. Dr. Griffith thought enucleation was on the whole satisfactory, cases being reported well five or more years afterwards. Iridectomy could not be recommended. In view of the fact that it was impossible to be quite certain if the disease were primary, and that some of the milder cases got well, he would enucleate only if the sight was destroyed or the eye becoming rapidly disorganised in spite of treatment, as in his own case.—Mr. LAWFORD quoted two cases of supposed primary tubercle of the iris in young children. In both enucleation was performed, and the general condition of the patients improved considerably; one was known to be alive and well three years afterwards. In these and in many of the recorded cases there was strong tubercular heredity. His own feeling was in favour of enucleating in cases of intra-ocular tubercle, as soon as there was moderate certainty that the eye was irremediably damaged; he thought the after-history of published cases justified this opinion, for in a fair

Digitized by Google

proportion the disease seemed to have been eradicated.—Mr. MCHARDY referred to a case of localised choroidal tubercle which he had brought before the Society last session, and in which he had removed the globe. The child, though delicate, was still in fair health. In cases of tubercular disease of the cornea, recovery sometimes occurred even when the affection was very severe. In localised choroidal tubercle, enucleation should, in his opinion, be performed; but in cases of tubercle of the iris he was often doubtful what treatment to adopt.—Mr. TWEEDY spoke of a young man who had been under his care at Moorfields for a year or eighteen months, in whom both irides were studded with little tubercular bodies. The eyes were slowly degenerating, in spite of all treatment. There was no personal or family history of either tubercle or syphilis.—Dr. TATHAM THOMPSON referred to a case of tuberculosis of the eye in which enucleation was followed by tubercular meningitis and death.

Mr. CHARLES WRAY (introduced) read a paper describing a form of Conjunctivitis observed by him after the application of Tea-leaf Poultices to the Eyelids. In a typical case there were swelling and congestion of the lid margins, congestion of the palpebral and ocular conjunctiva, especially in the line of the palpebral fissure. The caruncle and plica semilunaris were swollen, and presented a peculiar glistening translucent appearance. There was some sero-purulent discharge. Mr. Wray considered it most probable that the affection was due to micro-organisms.

The following patients and card specimens were shown:—

Mr. TREACHER COLLINS: Microscopic Section of Human Lens with Epithelium on the inner surface of the Posterior Capsule, and showing other structural peculiarities.

Mr. JESSOP: (1) Case of Aniridia with Dislocation of Lenses; (2) Case exhibiting a Punctate appearance of the Anterior Capsule of the Lens.

Mr. SILCOCK: Case of Symblepharon treated by Snellen's Operation (modified).

Mr. SPENCER WATSON: Osteoma of Infra-superciliary Region.

MEDICAL SOCIETY OF LONDON.

Adjourned discussion on Aortic Aneurysm.

A CLINICAL EVENING of the Medical Society took place on Dec. 16th, the President, Dr. Theodore Williams, being in the chair. A large number of cases of aneurysm were shown.

The PRESIDENT, in resuming the adjourned discussion on the Diagnosis and Treatment of Aortic Aneurysm, congratulated Dr. R. Douglas Powell on the practical character of his propositions, and especially on his attaching more importance to the pressure phenomena than to the cardio-vascular signs in the diagnosis of aneurysm. With reference to the relation which fusiform aneurysm bore to saccular, it must be remembered that both sometimes coexisted in the same patient. He had never heard the diastolic "shock-sound" except in cases of aortic aneurysm, but it was not always to be detected in these, and as for murmurs, they were quite as often absent as present. The relative importance of auscultatory phenomena and pressure signs depended principally on the portion of the aortic arch involved, aneurysm of the first portion usually presenting some physical signs in the shape of pulsation, dulness, shock, or murmur, and it was generally with this form that cases of aortic regurgitant disease with retracted lung were confused, but he thought that the position of the heart, the presence or absence of cardiac hypertrophy and the results of measuring the two sides of the chest were generally distinguishing features. In many cases of aneurysm of the transverse and descending portions of the arch the evidence of auscultation was often wanting, and that of pressure signs most important; the variations in this pressure in aneurysm from changes in the size of the vascular swelling often proved of assistance in the diagnosis. In these cases the presence of stridor, of metallic cough, and dysphagia with fixation of the left vocal cord, dilatation of the left pupil, and weakening of the left pulse generally signified aortic aneurysm, but he had published a case in the Proceedings where all these phenomena were present, and were after death proved to have been due to a sympho-sarcomatous tumour in the mediastinum, which was detected during life by the rapid extension of the dulness in more than one direction. Syphilitic glands might give rise to nearly all the characteristic pressure signs of aneurysm, for in one well-marked syphilitic patient of his, with enlarged cervical and axillary glands, stridor of voice and breath were present, with fixing of the left vocal cord, and tubular sounds were heard above both scapulæ, with sternal dulness and accentuation of the second sound of the heart. Under large doses of iodide of potassium the symptoms entirely disappeared, which was the result in a similar case, where in addition dilatation of the left pupil was noted. Nevertheless, stridor was of great diagnostic value, and sometimes the only means of detecting the presence of aneurysm. A man aged thirty-two was admitted into the Brompton Hospital with a history of emphysema and asthma, and during one of the asthmatic attacks stridor was noted. The spasms subsided under chloroform and he was free for weeks, but he died suddenly in an attack of syncope, and post-mortem examination revealed an aneurysm the size of a Seville orange springing from the back of the transverse portion of the aorta and involving the posterior pulmonary plexus. The presence of markedly tubular breathing above one or both the scapulæ was one of the most valuable signs in obscure cases, but no signs or symptoms could be absolutely relied on. We should only trust to a combination of the various phenomena to guide us to the right conclusion. He (the President) often experienced great difficulty in persuading the patient to adopt Tufnell's method long enough for a complete trial, but he obtained excellent results from the iodide of potassium treatment, while restricting the patient's liquids and confining him to one floor of his house or to the gallery of the hospital; in other words, limiting his exertions without keeping him in bed, and he thought this sufficient for many cases of aneurysm. Consolidation of aneurysms sometimes took place under conditions the very reverse of those of rest, as he witnessed in a shoemaker suffering from aneurysm of the ascending aorta, apparently pointing in the second intercostal space on the right side, and who, in spite of rest being enjoined, pursued his heavy labours at his last, with the result that six months later the tumour had sufficiently consolidated to withstand a blow from the patient's hand apparently without injury. The man died later of a posterior extension of the aneurysm. With regard to abdominal aortic aneurysms, many cases of vaso-motor paresis of the aorta were mistaken for it; and he well remembered one instance where what had been described as saccular aneurysm of the abdominal aorta disappeared after the removal of an ill-fitting truss which had compressed both iliac arteries.

Dr. QUAIN said that the cases which gave difficulty in diagnosis were the tumours which produced pressure signs and the cases of aneurysm which did not. He referred to the case of Mr. Liston, who died forty years ago. Though seen by many distinguished physicians, none could diagnose his lesion, which turned out to be an aneurysmal tumour pressing on the trachea and the adjoining parts. Since then, however, our methods of diagnosis had improved. He had seen iodide of potassium combined with rest do much good; at any rate, it made the lives of many patients tolerable. He related a case which showed the value of stridor as an early symptom of aneurysm.

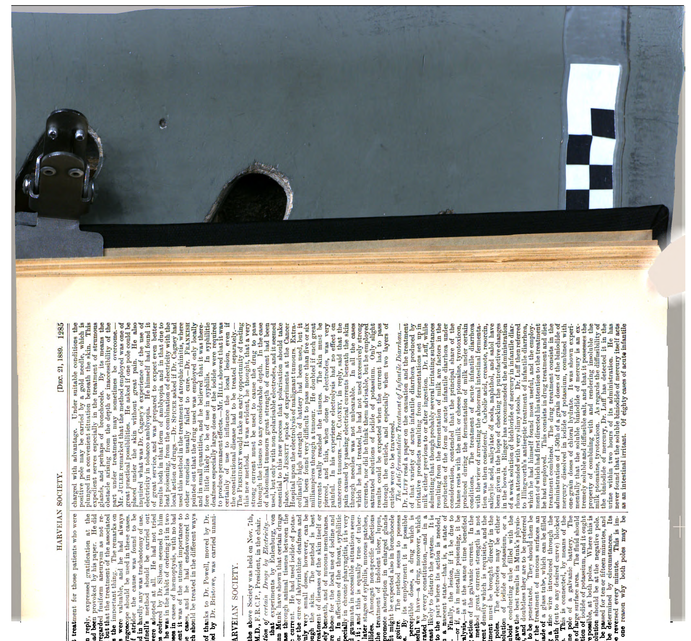
Dr. SEMON referred especially to the value of pressure symptoms as revealed by laryngoscopic examination. He said that nine years ago he laid down a law to the following effect: that whilst the adductors showed a great proclivity to be affected in various kinds of functional disease, the abductors were usually first affected, in all cases of gradually progressive organic lesion of the laryngeal motor nerves. If the abductor twigs only were affected, there would be no symptoms whatever, and the vocal cords would be found to stand a little nearer the middle line, and on phonation would come properly together. But gradually the opposing muscles underwent paralytic contracture, and the vocal cords became fixed in the middle line; this would produce no clinical sign, but would be found on laryngoscopic examination. Later, the internal thyro-arytenoid muscle became also affected, and then the voice was somewhat impure.

Dr. DE H. HALL said that pulsating empyemata were most difficult to diagnose from aneurysms, as were also malignant growths, but the latter could sometimes be told from the steadily downward course which they pursued. He was enabled to diagnose dyspnœa from direct pressure on the trachea from that produced by paralysis of the crico-arytenoidei postici by the entire absence of respiratory

Digitized by Google

excursion of the cords in the former instance. In administering iodide of potassium he thought Balfour's rule a good one—to diminish the dose at once when the pulse commenced to rise in frequency. In one case he found great benefit follow the application of an ice-bag to the chest in aortic aneurysm. He preferred aconite to digitalis as a quieter of the heart's action. In 96 per cent. of the cases of aneurysm Moore's treatment by introduction of wire would be injurious or useless. Aneurysm, from its tendency to impoverish the blood, increased the liability of patients to phthisis. In treatment it should be remembered that, as the original sac was filling with fibrin, another aneurysm occasionally developed further on. He exhibited two cases, both under the care of Dr. Sturges, at the Westminster Hospital. One, a man aged forty-nine, a smith's fitter, had been in the hospital since August, 1886, and the aneurysm commenced to develop eight months before that. There was pulsation in the second right interspace. The treatment was rest, but the diet was not particularly restricted; iodide of potassium was administered. He had been allowed to get up since March, 1888, and was since free from pain, though there was still a pulsating swelling. The second case was a waiter aged fifty-nine. He was admitted in October, 1889, with the history of a year's illness. In the left infra-clavicular region there was loss of resonance, with pulsation and well-marked diastolic shock. Laryngoscopic examination showed the left vocal cord in the cadaveric position.

Dr. MITCHELL BRUCE in his remarks devoted himself to treatment. He referred especially to five cases in which he had employed a combination of Tufnell's method with iodide of potassium. In the first case, that of a man aged forty-two, an aneurysm presented in the third left interspace. He was kept on his back for 207 days; given sixteen ounces of solid food and twenty-one of fluid daily; and sixty grains of iodide of potassium were administered in the twenty-four hours. At the end of that time he was comparatively well. He died about a year later after free living. In the second case, that of a woman aged fifty-six, an aneurysm lay behind the left sterno-clavicular joint. Strict rest was enjoined for 130 days, with seven ounces of solid food and twelve of fluid, and sixty grains of iodide of potassium. The patient was much better three years after the treatment, the tumour having disappeared. The third case was that of a woman, aged forty-eight, who had an aneurysm at the junction of the ascending and transverse arch, with double aortic disease. She was kept in bed for two months, and given forty grains of iodide daily, which effected considerable improvement. The fourth case, in a man of forty-seven, was much like the second, and, like it, did well. He was kept in bed for 105 days, given twelve ounces of solid food and twelve of fluid, with forty-five to sixty grains of iodide. The fifth case occurred in a woman aged forty-eight, who had an aneurysm of the ascending arch, and also one of the left common carotid. She was kept at rest for thirteen weeks, given ten ounces of solid food, with eight of fluid, with forty grains of iodide of potassium. At the end of six weeks the carotid aneurysm had consolidated, and at the twelfth week the aortic aneurysm was partly solid. The patient died suddenly two years later of aortic disease. Dr. Bruce was strongly impressed as to the value of the rest and iodide of potassium treatment, but said that the cases must be carefully selected. The treatment should be thoroughly carried out in every detail, and such adjuncts as morphine, antipyrin, &c., used when necessary. He showed an aortic aneurysm into which a short length of steel wire had been introduced and electrolysis applied. The wire was surrounded by a layer of decolourised fibrin, and there was evidence of commencing consolidation on the walls of the sac.



Dr. KINGSTON FOWLER said that though Dr. Powell had divided these cases into two classes, yet he had not implied that they could not be combined. A fusiform aneurysm was often associated with regurgitant aortic disease, but an aortic diastolic murmur was rare with sacculated aneurysms. Pain was a valuable symptom, and aneurysms were often overlooked through not paying attention to this. The prognosis of aneurysm with regard to duration of life was rather better than was usually supposed. One case he had watched to complete consolidation for eight years and a half, while another died of aortic regurgitant disease after an aneurysm had existed seven years and a half. He showed a case which he first saw in 1882; the patient was a musician, and blew a wind instrument. He was treated for four months with rest and diet combined with iodide of potassium, and he had been watched ever since. He had been at work since 1886. He was not clear as to which of the two parts of the Tufnell treatment—the rest or the diet—did the good, but he thought that the rest was of the greatest possible importance. It ought to be seriously considered whether patients should be compelled to be put to the intense suffering caused by the restriction of food, and especially of liquids in summer. He thought that there were certain contra-indications to the Tufnell treatment, such as the coexistence of aortic regurgitation, for the compensation of the left ventricle should be maintained, which could not be done under the Tufnell treatment. He was in favour of rest and iodide of potassium, and thought that diet was not of so much importance; he certainly would not make the patient excessively hungry or thirsty. Though he had deprecated wiring in one case in which it was adopted, yet he thought that in that instance it had prolonged life. He considered that life in most cases of aneurysm was shortened rather than lengthened by surgical procedures.

Dr. SEYMOUR TAYLOR said that the diagnosis of aneurysm presented some anomalies. There were only five physical signs proper to aneurysm—namely, abnormal dulness, pulsation over the dulness, bulge, thrill, and "diastolic jog," or shock. He thought that thrill was commoner than Dr. Powell seemed to infer; it was a common sign in saccular aneurysm near the surface. He looked upon the diastolic jog as a systole of the sac, aided by the recoil of the distended surrounding tissues; for its production it was necessary that the aortic valve should be fairly competent. He had seen it in abdominal aneurysm, and the sphygmogram of the femoral arteries would exhibit in such cases a marked "waterhammer" type. He had been in the habit of speaking of aneurysm of the first part of the arch as causing principally venous obstruction, of the second part as causing pressure on the respiratory tract and on nerves, whilst a sac in the third part most frequently impinged on the œsophagus and on the vertebræ. Syphilis he regarded as an unduly magnified cause of aneurysm, while heredity had been overlooked. He was glad to hear Dr. Bristowe speak against prolonged rest in bed, but in considering this question he would divide the poor from the rich; in the latter the effect of a prolonged rest, with the administration of iodide, should certainly be tried. He had seen ergot do good in the way of arresting pain, but the effect of alcohol, especially of ardent spirits, was baneful. He unhesitatingly condemned the intrusion of wires or of other foreign bodies into the sac.

Dr. ROBERT MAGUIRE showed five patients suffering from aortic aneurysm. One was a diver in the Chatham Dockyard, and it was probable that the atmospheric and other conditions of his employment had contributed greatly to the development of his disease. This patient, in addition to other signs of aneurysm, showed also bilateral paralysis of the abductors of the cords, with inspiratory stridor. This was a most valuable sign, occurring as it did when other symptoms were little marked. A second patient showed an aneurysm of the first portion of the aorta, illustrating the fact that such a position caused the appearance of physical signs, and not pressure symptoms. This patient showed well-marked signs of aortic regurgitation, and the sphygmograph indicated inequality of the radial pulses. As a rule the sphygmograph was not so valuable as the well-trained finger, but an exception must be made to this rule for aneurysm cases. Here the tracing, which showed a rounded summit, a gradual descent, obliteration of the secondary waves, and which also was obtained by pressing hard on the artery, was a very valuable indication. The third case showed pressure on the left bronchus; the fourth how an assemblage of slight symptoms would establish the diagnosis, when each alone would be useless; while the fifth case was one of aneurysm of the aorta involving the innominate artery. Dr. Maguire also referred to a sixth case, where the patient, given greatly to athletic exercises, had engaged to run a race one week after he was first seen. He had a most extensive aneurysm, and was quite unconscious that anything serious was the matter with him.

Dr. EWART exhibited two cases, one of simple dilatation of veins of the chest without other sign of aneurysm; it was relieved by treatment with iodide of potassium. In the second case there was protrusion of a tumour in the second interspace, and Tufnell's method of treatment, combined with iodide of potassium, had been adopted for a year and a half with great benefit; but fluid pulsation was still perceptible in the sac. He looked upon the combined

Digitized by Google

diarrhœa treated by this method, the diarrhœa ceased within two days in seventy-two of the cases; in five of the remaining eight cases it ceased within four days, and in no case did it last more than seven days.

Exposed Child with Spina Bifida.—Mr. J. J. CLARKE showed the body of a female child which died a few hours after birth at full term. Hydrocephalus, spina bifida, and double talipes were present. The spina bifida was a myelocele. When the head was pressed there was a flow of fluid from the aperture of the central canal at the upper end of the myelocele, which at the same time was lifted up by the increase of pressure in the cerebro-spinal fluid behind it. At birth both hips and knees were fully flexed. The feet were crossed and fixed by four turns of the umbilical cord. The right foot showed marked equino-varus; the left had similar characters, but was also flattened. Dissection of the right side showed that the anterior ligament of the hip and the posterior ligament of the knee were short, and prevented extension. The ligaments on the inner side of the foot were similarly shortened, and the bones were considerably altered in shape. The deformity appeared to be fully accounted for by the mechanical conditions. The microscopical appearances of the nerves and muscles were normal.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

Malaria v. More Recognisable Causes of Disease.

AT the meeting of the Society on Dec. 11th, Sir WILLIAM MOORE read a paper on Malaria. He observed that the diseases which malaria had been accused of causing comprised nearly the whole nomenclature; in fact, it put him in mind of the 122nd proposition of the Brunonian system, which declared debility to be the cause of intermittent as well as of every other kind of fever. But this direful agent malaria had not been discovered by chemical or any other means. All we knew of it has been deduced by inference from previous consequences. Sir W. Moore then mentioned the various theories which had been propounded as to the nature of malaria, the last being that of Crudeli and Klebs. After reviewing what had been advanced with regard to the bacillus malariæ, the speaker observed that various authors had stated fever might be induced in half an hour after exposure, so that malaria might kill at once; were we, therefore, to suppose that the bacillus entered the system, took up its habitat in the spleen and marrow of the bones which it is said to affect as retired residences, multiplied, issued forth, and excited fever all in half an hour? Moreover, the bacillus malariæ has not been found everywhere where ague-ish disorders occur. It was said to require moist earth on which to germinate, but malarious fevers occurred on dry sand and on rock, where there was not the required moist earth. Further, either would it be reasonable to suppose that every kind of earth surface would produce the same bacillus. Reasoning on analogy, because a particular appearance is found in the blood of persons living in a particular locality, that such is the cause of the disease. The filaria sanguinis hominis, which Manson theorised as the cause of elephantiasis, is found in the blood of many persons apparently quite healthy. Similarly with the spirillum, presumed to be distinctive of relapsing fever. Then what becomes of the bacilli? They must leave the patient or he would not recover. But they do not infect the atmosphere or clothes, or the disease would spread through them. If after passing through the human body they are incapable of reproducing themselves, they must exist independently wherever malarious diseases occur, which, as above stated, it is not reasonable to presume. Again, everyone admits that secondary attacks of ague may occur months or years after the primary attack. Are we to suppose that the bacilli remain in the system for months or years seeking for an opportunity to manifest their presence? But it has been stated that inoculations of the bacillus have produced ague. Not everyone can be placed on this. In a malarious country nearly everyone suffers from fever at some time or other. The very fact of inoculation proved it were known what it was for, would excite an attack in a nervous subject even without the hypnotic sleep and "suggestion," of which we have heard so much recently. With reference to the existence of fever on sandy soils, where there is not the moist earth of the Roman maremma for the bacillus to vegetate in, Sir William Moore vividly portrayed the semi-desert district of western India as compared with the southerly district, such as the Deccan, where on the latter, with rich soil and abundance of moisture, the climate, the ground, was black alluvial earth. In the one water was 300 or 400 feet from the surface, in the other 3 or 4 feet. In the one there was not more than 5, 6, or 7 inches of rain annually; in the other 80 or 90 inches. In the one vegetation was of the most scanty description; in the other most profuse. In the one there were no swamps; in the other the whole country was intersected by tidal rivers, and was more or less swampy. The one country was exposed to the fierce hot winds of the desert; the other to the sea breeze. Yet in these districts, so different, malarious disease in proportion to population prevailed to about the same extent. The only resemblance was rapid alternation of temperature, with at some seasons excess of humidity. Then as regarded the prevalence of malarious fevers on rock, the same alternation of temperature was the case. A rock under a tropical sun in the daytime might be hot enough almost to cook a mutton chop, and at night fall almost to a cold and freezing point, the change accompanied by profuse dew. Of course, the neglect of this was a characteristic of malarious disease, there was no periodicity in a large spleen. Agues even were often so irregular as to lose all claim to periodicity, which implies regularity. Hectic fever, relapsing fever, and syphilitic fever were all periodic, but no one attributed them to malaria. There was periodicity in enteric, and even in continued fever. In fact, periodicity was a law of nature. When epidemics of so-called malarious disease presented among troops, or among civil populations, there were always other causes of disease recognisable. Instances of this were given, and of individual cases of fever there were few which could not be traced to a chill contracted in some way or other. We were formerly taught that congestions and inflammations were originated by the rush of blood to internal organs consequent on a chilled surface, and probably this teaching was not incorrect. It is more recently advanced that chill indicates disturbance of protoplasmic action, so-called cooling down in a climate of change, and that "bodies" are formed in the secretions which may be veritable poisons. Why one person should get a liver abscess and another a fever from a chill might perhaps be explained by predisposition on the part of the organs affected. If this existed, fever would probably not be the first consequence. Exposure to prolonged heat caused first excessive action and then debility of the skin, which resulted in great liability to chill in tropical climates, a very slight reduction of temperature being there excessively felt. And most tropical climates are noted for great seasonal and diurnal changes. A person in the sun may experience 120° of heat, and at night a temperature of almost freezing point; such changes excite opposite physiological processes, and may be repeated in a spasmodic form, exactly as was the case with M. Brachet, who, after bathing several times at a certain hour in the cold river, experienced an attack of ague the first night he did not so. The intensity of so-called malarious disease may be estimated by the degree of change. Thus, the greatest agues occur in the equator, they are rarely found in insanitary localities, and they occur in the autumn, when changes of temperature are greatest, damp being added to cold; for damp cold has a greater power of abstracting heat than dry cold. The prevention of so-called malarious fever did not consist in stopping the formation of malaria, but in protection from sudden changes of temperature, from damp, from night exposure, especially when asleep, and in maintaining the vigour of the system by suitable diet. His position was briefly this. That so-called malarious fevers are caused by sudden abstraction of heat, or chill, under the influence of cold, and more especially of damp cold; that these effects of chill are more marked in hot climates, because of the antecedent exposure to great solar heat, the anæmia and skin debility resulting from heat, and the disregard of suitable precautions; that the individual malady will be of a febrile character in the absence of predisposed or diseased conditions of organs, but that it will assume other forms if these exist, or not according as temperament, heredity, habit, mental condition, anæmia, recurring chill, one or more, favour such repetition; that so-called malarious cachexia or anæmia is the result of the operation of heat on the system.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

A MEETING of this Society was held on Dec. 13th, Mr. Armstrong, President, in the chair.

Dr. REGINALD DUDFIELD read "Some Suggestions for a Revision of the Tables of Causes of Deaths." The need for such a revision, and the desirability of having it completed before the next census, were, he said, strongly felt by statisticians and sanitarians, and he thought that a conference of representatives of societies interested in the question, with others of the Royal Colleges, should be convened for the purpose. He exhibited in parallel columns the tables drawn up by the Society in 1874 with a view to secure uniformity in the reports of medical officers of health, those adopted by the Registrar-General in 1881, and his own. Any such classification should consist of a minor and a major scheme, for the use respectively of medical officers of health and of the Registrar-General, as well as of county authorities, differing only in the minuteness of the subdivisions. The conditions of the population as regarded number, distribution, and density, the relative proportions of the sexes at different age periods, the increase or decrease in the last decennium &c. were necessary to give real value to mere numerical statements; but a most important consideration was the calculation of the death-rates of infants under one year, and of children under five years of age on the numbers living at those ages. The common practice of calculating these deaths on the total population or on the deaths from all causes at all ages was utterly useless, since the proportion of infants and children to adults differed greatly in different communities. The local meteorology should be recording according to Mr. Glaisher's tables. The selection of the cause of death from among two or more diseases certified as occurring together or consecutively called for more precise instructions to superintendent registrars, and uniformity in the returns of medical officers was much to be desired.—In the discussion that followed, the necessity for breaking up the first class was pointed out by Dr. Newsholm, since some diseases, as measles and whooping-cough, had no relation to the sanitary conditions of a community of which the gross zymotic death-rate gave no true indication; while, as Drs. Corfield and Sykes observed, the medical officer of health was really concerned only with such diseases as were more or less preventable. and might well throw together as from "other causes" the majority of local diseases.

Mr. ST. CLAIR SHADWELL then read a short paper on the Need for Infectious Hospitals in the Extra-Metropolitan Suburban Districts, the populations of which were increasing with extraordinary rapidity, and in many places fearfully overcrowded. The public should be taught that such hospitals were not foci of contagion, but afforded the only means of isolating infectious cases occurring among the poor. He believed that in most instances the expense was the sole obstacle to their erection, and pointed out that, while Section 131 of the Public Health Act permitted the combination of districts for this purpose, Section 139 empowered the Local Government Board to compel such combination—a power which, he urged, ought at once to be put in force, although, in his opinion, the charge would be better laid on the county rate, as was that of lunatic asylums. To illustrate the urgent need for these hospitals, he stated that to his knowledge two cases of scarlatina on a farm had led to an outbreak in his own district with several deaths, and probably to many more in London, where the milk was consigned.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

THE opening meeting of the Surgical Section was held on Nov. 8th.

The PRESIDENT (Mr. Meldon) delivered an address on general subjects of surgical practice, giving scope for progress.

Operative Treatment of Tubercular Disease of the Knee-joint.—Mr. THOMSON read a paper on the Operative Treatment of Tubercular Disease of the Knee-joint. Having referred specially to the infective character of tuberculosis, he pointed out that where the condition of the synovial membrane demanded operation the disease was rarely so limited as to be moved by simple erasion. In some cases where the cartilages were apparently quite healthy the bone was found on section to be diseased, and yet this was the sort of case which the thoroughgoing eraser would regard as typical for his treatment. The securing of movement after erasion was being abandoned, and that being so, anchylosis could be more surely and quickly secured between two level bone surfaces, as in excision, than by the opposition of two irregular cartilage-covered surfaces. Shortening sometimes occurred where no operation was done, so that this objection could not be fairly argued as a result of excision. If the disease was extensive enough to lead them to the epiphysial line, they must go there even at the risk of shortening. He maintaind that excision was safer and more satisfactory than erasion. He had excised the knee seventeen times without a death; but in two of his cases, before adopting the combined methods of fixing by Thornley Stoker's dowels, and the use of his own hoop-iron splint, he had to amputate. In his hospital in fifty successive cases of excision of the knee-joint there had only been one death—a result which left little to be desired.—Mr. TOBIN thought that Mr. Thomson had not indicated clearly what cases ought to be submitted to operation, nor had he suggested an answer to the difficult question—"Shall I operate at once, or wait, and if I wait, how long?" It was important to determine whether an operation should be performed at once in every case diagnosed as tubercular synovitis, or whether it would be desirable to wait until the bones were attacked, or still longer till suppuration had set in. For his own part, he would wait longer than Mr. Thomson seemed to approve, having regard to the fact that by the use of Thomas's splint, complete rest and change of air, he had seen great cures effected. Moreover, he did not see that a resected knee had much advantage over an amputated leg supported by the modern improved artificial appliances. However, as regards the method of excision, he could not speak too highly of Mr. Thomson's operations, but he differed from Mr. Thomson on the advisability of early operation. He had tried Mr. Stoker's pegs, but in the cases in which he used them they gave little or no fixation. He sometimes found that while a straight limb was obtained for three or four years it afterwards became crooked.—Sir WM. STOKES endorsed Mr. Thomson's views as to the superiority of excision of the knee over the operation of erasion or arthrectomy. As to the time for operation, it was impossible to lay down a rule; but, speaking from his own tolerably large experience of the operation, he held that as soon as the surgeon satisfied himself he had to deal with tuberculous disease of the joint, the earlier the operation was performed the better was likely to be the result. He repudiated the statement put forward in more than one handbook of operative surgery, that knee-joint resection would soon be an operation merely of history. On the contrary, the operation never enjoyed a greater reputation than at present, and he believed its reputation was likely to increase. He did not at all agree with Mr. Tobin's estimate of amputation. The results from excision achieved both by his former colleagues and himself in the Richmond Hospital had been eminently satisfactory. He preferred a splint which he himself had devised to Mr. Thomson's, as ensuring absolute fixation and rigidity of the limb, and also as rendering unnecessary the dowelling as recommended by Mr. Thornley Stoker.—Mr. J. K. BARTON, referring to the question raised by Mr. Tobin, of the general advisability of the operation, said the real point was as to the procedure, and he had no doubt there were cases of disease of the synovial membrane in which erasion might be profitably performed instead of excision; but erasion could not be favourably compared with, or take the place of, excision in cases of tubercular disease. He did not sympathise with Mr. Thomson's advocacy of the removal of sound bone, but otherwise he agreed in the main with Mr. Thomson's views. Instead of Mr. Stoker's pegs he used strong antiseptic catgut, which did not yield until danger had passed away.—Mr. LENTAIGNE concurred with Sir William Stokes that excision was the best treatment for tubercular disease of the knee-joint, and ought to be performed as soon as the disease was recognised; and if the limb became crooked afterwards, it was the fault either of the surgeon or the patient, and very often of both.—Mr. BENNETT questioned the dictum that excision was the proper and right treatment once the diagnosis was tubercular disease. The vast majority of such cases in the upper classes were treated without excision. Patients had recovered from white

Digitized by Google

swelling of the knee with all the due care and rest that could be given in private practice. But where tubercular disease was running riot there was no longer the alternative of palliative treatment, and it then became a choice between excision and amputation. At the same time he had seen cases of recovery take place even after suppuration had set in.—Mr. SWAN observed that the spontaneous cure alluded to by Mr. Bennett was the established practice of a great many eminent London surgeons, including Howard Marsh and Owen, the latter of whom had extensive practice with children, and believed in letting the joint suppurate; but the average period of cure was three years—a longer time than could be afforded for hospital patients.—Mr. FRANKS said he had himself operated by excision for tubercular disease of the joint, in the case of a female patient, with success, as Mr. Swan and Mr. Barton could testify.—Mr. THORNLEY STOKER held that whereas excision was an operation of established repute, yet that of erasion was on its trial, and accordingly no decisive opinion could be expressed about it. As regards the time to operate, he had frequently had cause to regret delay, but he had never had cause to regret the premature performance of the operation.—Mr. CORLEY submitted that when the surgeon recognised pulpy thickening of the knee-joint, as it was called in the nomenclature of Sir Benjamin Brodie's day, palliative or medical treatment was worthless, and the sooner the patient got the chance of a good limb by operative procedure the better.—Mr. WHEELER held that where excision was necessary it should be done early.—Mr. THOMSON, in replying, said he had advisedly narrowed the scope of his communication by omitting conditions anterior or preliminary to the question of excision *versus* erasion, two operations which he found pitted against each other. As to the time to operate, the sooner the better, once the surgeon saw distinct pulpy degeneration of the synovial membrane. It was impossible to lay down a fixed rule as to the particular moment in a particular case. Every surgeon must be guided by his own experience. He did not think that Mr. Tobin was serious in comparing the results of resection and amputation. He regarded his observations as jocular. As to erasion, he could understand the procedure where there was perfectly localised tuberculosis that could be fixed and taken away; but the moment it became necessary to open the knee-joint and erase the synovial membrane as a whole, it was much better surgery to make a section, and excise the knee in the ordinary way. No doubt there were cases that got well, even though suppuration had set in, but the surgeon who had faith in expectant treatment must remember that he was running the cure of the knee against the patient's life; that he was running the risk of losing the limb altogether, and setting up the seeds of mischief which would ultimately carry off the patient.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

THURSDAY, DEC. 5TH.

DR. GWYNNE, PRESIDENT, IN THE CHAIR.

Aneurysms.—Dr. HARGREAVES showed a specimen of Aneurysm of the Abdominal Aorta, just above the bifurcation. The sac was posterior, resting on the vertebræ, and of the size of a small orange. The patient, a man aged thirty, was a grinder, and the probable cause of the aneurysm was a strain in lifting a grinding stone. The cause of death was rupture of the sac into the abdominal cavity.—The PRESIDENT showed a specimen of Aneurysm of the first part of the Descending Thoracic Aorta. The patient was a healthy woman, aged thirty-six; married; no family. There was no history of gout, rheumatism, or syphilis, or of any injury. She complained chiefly of acute neuralgic pains shooting from the spine to the left infra-mammary region. She died about a year after the symptoms appeared. There were no other pressure symptoms. Post mortem an enormous aneurysmal sac was found filling up the entire cavity of the left chest. The necks of three ribs were eaten into, and the bodies of the corresponding vertebræ were eroded so as almost to expose the cord. The patient's only business was looking after a small baker's shop.—Dr. PORTER showed a specimen of Aneurysm of the Ascending and Transverse Aortic Arch. The symptoms had been those due to pressure on the trachea at its bifurcation, and on the root of the right lung. The patient, a man aged forty-eight, died of asphyxia.

Epithelial Cancer of the Vulva and Vagina.—Dr. KEELING showed this specimen, removed from an elderly single woman at the Jessop Hospital. An operation had been performed on the same patient twelve years before, the disease at that time occupying the clitoris and fore part of the vulva. The old cicatrix and neighbouring tissue had remained sound, the return of the disease being in the posterior half of the vulva, extending from this point up the vagina.

Strangulated Hernia.—Dr. KEELING also read a paper on two unusual cases of strangulated hernia, operated on in the Public Hospital and Dispensary.

Dislocation.—Mr. GARRARD read notes of two cases of joint dislocation. In one, a man aged forty-four had sustained a dislocation of the right femur on to the dorsum ilii, and of the left femur into the thyroid foramen, with other injuries, including fractured ribs and arm. The other case was one of subcoracoid dislocation of the humerus in a young man of five weeks' duration, which he reduced with difficulty by Kocher's method, after other means had failed. He asked the question whether it would not be justifiable in the case of a young man with a comparatively recent irreducible subcoracoid dislocation to open the joint, with the minimum of damage to the circumflex nerve and deltoid muscle, between the two heads of the biceps, clear out the glenoid fossa, and restore the head of the bone to its correct position, rather than leave the case to nature. He thought that a movable joint ought to be secured.

CARDIFF MEDICAL SOCIETY.

THURSDAY, DEC. 5TH.

MR. A. P. FIDDIAN, M.B., IN THE CHAIR.

Periostitis as a Cause of Death in Children.—Mr. A. P. FIDDIAN, M.B., read a paper on this subject. Two cases were described, in one of which the symptoms came on shortly after an accident, and ran so acutely that the whole leg became swollen from the foot upwards as far as the hip, and death ensued in six days. Post mortem, the tibia was found lying quite loose, bathed in pus, and the tissues of the thigh infiltrated with serum. In the other, a child of three, the illness began with convulsions, high temperature, and pain and swelling in the leg. It lived only fifty-six hours from the commencement of the seizure, and after death the shaft of the tibia was discovered to be bare, with a watery fluid around it.

Case of Extra-uterine Fœtation.—Dr. CAMPBELL gave the history of this case. Sixteen years ago the patient, thinking herself pregnant for the third time (eighteen years having elapsed since the last), engaged a nurse to attend her. Labour pains came on, but no progress was made, although a medical man who saw her pronounced her pregnant. After a week in bed she got up, but continued ill more or less for the next three years, and when Dr. Campbell saw her then for the first time the signs of a large abdominal abscess pointing near the umbilicus were present. This discharged for a few months, but after the sinuses had been closed for some time a large ventral hernia made its appearance. A binder supported this efficiently, but she used at intervals to suffer from abdominal symptoms, and finally died in October of intestinal obstruction at the age of fifty-eight. At the necropsy there was found in the pelvis a mass of stony hardness about the size of a child's head, occupying the seat of the uterus and right broad ligament. It was freely movable in all directions. On section with a saw, it contained an almost complete set of fœtal bones enclosed in a calcareous capsule. The immediate cause of death was the constriction of a knuckle of small intestine by a band of omentum.

TAUNTON AND SOMERSET HOSPITAL.—The annual report of the Taunton and Somerset Hospital and Victoria Jubilee Nursing Institute for 1889 shows that the total general income was £3765, and the total general expenditure £4448. A long-felt want in the working of the institution has been supplied by the provision of a casualty ward near the principal entrance, thus obviating the necessity of taking casual patients at once into the general wards. Important improvements have also been made in the sanitary arrangements of the hospital. Funds are urgently needed to carry out other important improvements and additions recommended by the medical staff.

Notices of Books.

A Manual of Pathology. By JOSEPH COATS, M.D. Second Edition. London: Longmans, Green, and Co. 1889.—The author of this valuable text-book has evidently spared no pains to render the second edition more complete than the first, besides submitting the book to a thorough revision. He has added chapters upon the nature and causation of disease in general, and upon teratology in the General Part; and in the Special Part, chapters upon the thymus and thyroid, and upon the eye and ear. A reperusal of the book confirms the favourable impression originally formed of it as an excellent, clearly-written, and comprehensive treatise, which occupies ground not so fully covered by any other English text-book. The opening chapter on Causation is suggestive in the statements put forward to show that almost all disease is due to the lack of resistance on the part of the tissues and cells to external agencies; such susceptibility being enhanced by congenital or inherited peculiarities, as well as by the circumstances of the individual life. The wide subject of teratology is briefly dealt with and systematically arranged, but the lack of illustrations to this part somewhat impairs its value. Under Thrombosis we fail to find any reference to the remarkable researches of Wooldridge, which, if substantiated, considerably modify the doctrine of coagulation enunciated by Schmidt and A. Buchanan, which is adopted here. The description of the Inflammatory Process and the sections upon Syphilis and Tuberculosis are very clearly written. As to the section on Tumours, the subject of cysts, always a difficult one, might with advantage have been more fully treated, particularly in connexion with the recent suggestive statements of Bland Sutton. Bacteriology, which has added so much to the labours of all writers on pathology, is dealt with succinctly and with critical acumen. We note that the author regards both Fränkel's and Friedländer's "pneumococci" as belonging rather to the group bacillus than to that of micrococcus, and he suggests, what is highly probable, that pneumonia may possibly have relations to other bacteria besides these two forms. The extensive *rôle* assigned to Fränkel's "diplococcus" as a cause of other inflammatory affections than pneumonia should also be borne in mind. The subject of pyrexia is introduced by physiological considerations on normal heat-production and its regulation, and the various theories of fever are impartially discussed. The morbid anatomy of the various organs, which forms the Special Part, and occupies about two-thirds of the volume, is notable for its systematic and methodical descriptions. We might particularise the sections upon diseases of the heart and bloodvessels, the nervous system, lungs, and female generative organs as samples of the thoroughness with which Dr. Coats has undertaken his task; but, indeed, the whole is complete and well-proportioned. The illustrations are very numerous and excellent, and the book has been produced in a manner highly creditable to the publishers. We have no doubt that it will continue to be widely read and consulted by teachers as well as by students.

Cancer and its Complications. By CHARLES EGERTON JENNINGS, F.R.C.S., M.S., M.B. London: Baillière, Tindall, and Cox. 1889.—We confess to some disappointment on a perusal of this work, for we not unnaturally looked for some new light to be thrown either upon the nature or treatment of cancer. On the other hand, the work can hardly be regarded as other than a fairly careful compilation of well-established facts, intended to emphasize the local origin of malignant disease, and the need for its early and entire extirpation. Although embracing under the term "cancer" all varieties of sarcoma, as well as of carcinomata, it will be found that the author deals more especially with the latter in his subsequent chapters. He reproduces at considerable length the debate on cancer before the Pathological Society in 1874, and includes in the book statistics of amputations furnished by Mr. Page of Newcastle, besides freely citing cases published by other authors. It may be noted that he believes Chian turpentine to have "a specific action of some sort" upon cancer (p. 66), and thinks there are undoubted cases of cure by its use. Whilst giving Mr. Jennings every credit for his object in writing such a book—and in our view the doctrine he enforces is the most reasonable and hopeful one to be taken of this class of disease,—we cannot help thinking that he has been too ambitious. The subject of cancer in all its bearings has grown to vast proportions, and those who would advance our knowledge of it must be prepared to devote many years to its study. There is room for such a treatise in medical literature, but it must be comprehensive and exhaustive, pathologically and clinically complete.

L'Œuvre de C. J. Davaine. Paris: J. B. Baillière et Fils. 1889.—*Traité des Entozoaires.* Par C. DAVAINE. Deuxième Édition. Paris: J. B. Baillière et Fils. 1877.—The name of Davaine, who died in 1882, will always be linked with the history of the pathology of septic disease. To him is owing the discovery in 1850 of the bacillus anthracis, which he termed *bacteridium*, and numerous experiments upon the true significance of this micro-organism in that disease. To him also we owe much concerning the interpretation of septicæmia. Davaine may, indeed, be said to have been the forerunner of Pasteur and Koch in those departments of inquiry with which their names are associated. Besides this work, he pursued during his industrious life many other scientific investigations. His classical monograph upon the entozoa, for instance, will bear comparison with the perhaps better known works of Cobbold and Leuckart. This is the second of the two books named above, which has been courteously sent to us by M. A. Davaine, who has edited the first-named volume, containing the collected writings of his father upon anthrax, septicæmia, bacteria, parasites, teratology, &c.—many of the articles being reproduced from the "Dictionnaire Encyclopédique des Sciences Médicales." The volume is prefaced by a memoir of the author, from the pen of Professor Laboulbène—a memoir read before the Société de Biologie, of which Davaine was one of the first members, and at which so many of his researches were presented.

The Asclepiad. No. 24, Vol. VI. By BENJAMIN WARD RICHARDSON, M.D., F.R.S. Longmans, Green, and Co. 1889. Dr. Richardson has selected for the subject of his memoir in this issue of his interesting journal Sir Francis Bacon, as a master of physic, and, as usual, presents his readers with an admirable autotype portrait. Bacon occupies so prominent a position in science that the inclusion of his name in the list of those already given by Dr. Richardson is fully justified. Needless to add, the memoir is written *con amore*, and is full of the wise precepts of Bacon upon matters pertaining to physic. In "The Medical Pilgrim's Progress" Dr. Richardson reproduces an introductory address he delivered thirty-two years ago at the Grosvenor School of Medicine, and the present generation will be glad to hear the hopeful and helpful words addressed to their precursors, and will benefit by them. Continuing his studies on the synthesis of disease, Dr. Richardson deals with melancholia, dreams, and delirium, as influenced or induced by the action of sulphur compounds (especially mercaptan), and he also summarises his views upon zymosis. There is much in his suggestive thoughts worthy of reflection, and it may be recalled that, to a certain extent, Bouchard has followed similar lines in his main pathological inquiries. Another paper, "Medicine

Digitized by Google

and the Alcohol Controversy," is, as may be expected from its author, thorough and uncompromising. No doubt a considerable and beneficial change has taken place in the attitude of the profession on this subject, but not to the extreme limits advanced by this earnest temperance reformer.

Manuel Pratique de la Garde-Malade et de l'Infirmière. Publié par le Dr. Bourneville, aux Bureaux du *Progrès Médical*. 4me Edition, revue et augmentée. Paris, 1889.—There are few more indefatigable in the cause of medical relief than the able editor of the *Progrès Médical*, Dr. Bourneville, who is also director of the municipal schools of nursing; and amongst his numerous useful undertakings none have been more appreciated than the courses of instruction for nurses which he organised in the latter capacity. In connexion with this scheme he published a series of handy volumes, containing the text of the lectures delivered to the nurses by competent teachers. The series has now reached its fourth edition and embraces five volumes, treating of all branches of knowledge required by the trained nurse, so that the publication may be held to constitute a veritable manual of the art and science of sick nursing. The instruction appears to us to be admirably adapted for the purpose in view, being conveyed in simple language and not overburdened with detail or theory. Prefixed to the first volume will be found the full syllabus of the courses as carried on at the Bicêtre, Salpêtrière, and la Pitié Hospitals. These volumes comprise—1. Anatomy and Physiology. 2. Hospital Administration and Management, &c., which embraces an interesting descriptive account of the foundation and maintenance of the Paris hospitals, and of the nursing profession, in which is to be found a defence of the action taken to replace the religious orders of nurses by lay bodies, an action diversely viewed in many quarters. 3. Dressings, which, by itself, forms an excellent manual of surgical nursing. 4. A volume devoted to various topics, such as lying-in, the care of the insane, the administration of drugs and the forms in which they are given, besides a vocabulary of medical terms. 5. Hygiene, in which M. Sollier in twelve lectures, four of which are devoted to the important subject of diet, has succeeded in imparting a large amount of useful information. Whatever may be thought of the wisdom of the measures taken in Paris to reorganise the system of hospital nursing, there can be no two opinions upon the desirability of imparting to nurses such an amount of scientific information as may increase their competence and awaken their intelligence. Over and above all such knowledge there must always be the essential attributes of patience, kindness, gentleness, and devotion, without which no one can claim to be a thoroughly efficient nurse.

Irish Medical Practitioner's Guide. By Professor R. J. KINKEAD, M.D. Dublin, with a preface by A. H. JACOB, M.D., &c. Dublin: John Falconer, 1889.—This substantial work, which contains specially valuable information for medical practitioners in Ireland, and particularly for those holding public appointments, such as poor law, infirmary, prison, lunacy, Admiralty, military, police, medical officers of health, and public vaccinators, is published by and with the authority of the Irish Medical Association. The care of the sick population in Ireland devolves to a very great extent upon State-supported functionaries; accordingly his responsibilities are so much the greater, and it is with a view to explain those responsibilities and how best they may be fulfilled that this book has been written. The third portion of the volume before us is devoted to epitomising the law by which the practice of the profession at large is governed, without special reference to the Irish medical services. A chapter on "malpraxis" serves a good purpose by enabling the medical practitioner to avoid the many pitfalls which the exigencies of practice place in his way. We can recommend this book for perusal and study.

The Victoria Cross: by whom, where, and how won. By T. E. TOOMEY, late Colour Sergeant, 1st Battalion, the Royal Irish. Pp. 67. London: Boot and Son. 1889.—This little volume gives a nominal return of all who have gained the Victoria Cross, with the acts for which in each instance it has been awarded. The Order was instituted in 1856, but a considerable number of officers and men were decorated for acts of valour done in the Crimean War. It has been conferred on 404 persons, the first having been Mr. (now Rear-Admiral) Lucas, and the last, Surgeon Crimmin of the Bombay Medical Service (since the issue of the book Surgeon Le Quesne has also obtained the Victoria Cross). Of the total number, 178 were commissioned officers, 3 in the Indian Civil Service, ranking as officers, and 223 warrant officers, non-commissioned officers, and men. Of the commissioned, 15 were medical officers and one an army chaplain; of the non-commissioned, one was lance-corporal, Army Hospital Corps, and one, hospital apprentice, Indian Medical Service. With the exception of one, who was decorated for rescuing twenty-five men from drowning, at Andaman Islands, the medical officers all had the Cross conferred on them for services connected with the wounded in the field. The proportion of medical to the other officers is one in twelve. Of the 404 who gained the Cross, 211 are believed to be still alive, and 64 to be still serving. Of the medical officers, the names of 13 still appear in the Army List, but only one of them is now on the effective list. The book appears to have been carefully compiled, and is interesting as a record of deeds of valour.

Guide Médical à l'Exposition Universelle Internationale de 1889 à Paris. Par MARCEL BANDOUIN. Premier Fascicule. Paris: Aux Bureaux du *Progrès Médical*, et R. Lecrosnier et Babé. 1889.—Those who visited the Paris Exhibition, and others, will be glad to have in permanent form some record of the exhibits in the wonderful collection now being dispersed. M. Bandouin deserves thanks for editing this "medical guide," of which this first fasciculus contains descriptions (amply illustrated) of all the novelties in surgical and scientific instruments exhibited by various makers of European reputation. The utility of so carefully edited a catalogue need hardly be pointed out, and its publication should be much appreciated.

By Pike and Dyke: a Tale of the Rise of the Dutch Republic. By G. A. HENTY. With Page Illustrations. London: Blackie and Son, Old Bailey.—*Grettir the Outlaw: a Story of Iceland.* By S. BARING-GOULD. With 20 Page Illustrations and Map. Blackie and Son.—*The Hermit Hunter of the Wilds.* By GORDON STABLES. With 4 Illustrations. Blackie and Son.—*Down the Snow Stairs.* By ALICE COCKRAN. With 60 Illustrations. New Edition. Blackie and Son.—*Laugh and Learn: the Easiest Book of Nursery Lessons and Nursery Games.* By JENNETT HUMPHREYS. Profusely Illustrated. Blackie and Son.—Messrs. Blackie and Son have effectively contributed to the illustrated literature of the season by the issue of the above enumerated handsome volumes. They do not make special claim to our notice as medical journalists, but none the less are they worthy of mention here, not alone on account of the value of their literary contents, but also for their pictorial wealth and the taste with which they are got up. The first three of the above-mentioned books are tales of adventure, and that of a wholesome and instructive kind, either of them being eminently suitable as a present for boys, who cannot fail to be delighted with the stirring narratives of personal prowess exhibited by the heroes of the stories. The fourth on the list is intended for the delectation of the youth of both sexes, but more especially

Digitized by Google

for girls, and presents, under the guise of a fairy tale, much information of a useful character in a form easily assimilable by the juvenile mind. The last-named is addressed to very young readers, to whom it will be welcome as combining unlimited amusement with pleasant means of instruction.

Love of Money the Root of all Evil. By ALEC FEARON. London: Swan Sonnenschein and Co. — This is a cheerless book, in which the worst side of human nature is portrayed with a relentless fulness and realistic detail. Its moral, coming when it does, appears to be that it is quite possible for a prisoner falsely accused of poisoning to be convicted on inconclusive evidence. That this is so one would hardly venture in general terms to deny; but the sad fate of Nellie Parsons was brought about not only by the most extraordinary sequence of untoward events, but also by singular supineness and precipitation on the part of those whose province it was to be her friends. The plot, though interesting, is not strong enough to prove much; but in truth we suspect that the writer's ambition is rather to be vivid than convincing. Vivid he is; and if his subject were less distressing, his portrayal of it would be delightful. As it is, there are many readers who will find fascination, and even charm, in its dense shadows and lurid lights. We, for our part, prefer to read for amusement less melancholy books.

Medical Diaries &c. for 1890.—We have received a large assortment of medical diaries and pocket-books for 1890, all of which appear to be at least equal to their predecessors in completeness and finish. The specimens forwarded by Lette's Diaries Company, Royal Exchange, E.C. (Publishers: Cassell and Co., Limited, London, Paris, New York, and Melbourne), are accompanied by an interesting little pamphlet, entitled "Notes on Celebrated Diarists and their Diaries." Amongst others, accounts are given of the diaries kept by that prince of diarists, Mr. Samuel Pepys, who for ten years entered up his journal with exemplary regularity, filling six volumes closely written *in shorthand*; of General Gordon, to whose diary, written, in the absence of a pocket-book, on the backs of telegram forms, we are indebted for the only reliable narrative obtainable of the events which led to his death; of Dr. Livingstone, who in his notes, written on old newspapers, has handed down to posterity an invaluable record of the habits of men, animals, birds, and fishes in Africa; and of Charles Dickens, who was a habitual diary keeper. Whilst endorsing Captain Cuttle's excellent advice, "When found make a note of," we think it hardly necessary to carry the practice out with the scrupulous exactitude of the worthy Mr. Pepys, in whose diary we find the following amongst many similar entries:—"Mar. 13th, 1664-5: 'This day my wife begun to wear light-coloured locks, quite white almost, which, though it makes her look very pretty, yet, not being natural, vexes me, that I will not have her wear them.' Sept. 17th, 1666: 'Up betimes and shaved myself after a week's growth; but, Lord! how ugly I was yesterday, and how fine to-day.'" As a complete pocket companion for medical practitioners, we can recommend Lette's "Ideal Medical Diary;" but, indeed, the variety of pocket-books and diaries issued by this firm is so extensive that the most exacting requirements can be suited.—A handsomely got up pocket-book is "Smith's Visiting List, Physicians' and Surgeons' Diary, Almanack and Book of Engagements" (forty-fourth year), published by Hazell, Watson, and Viney, Long-acre, W.C. In addition to the ruled pages for the visiting list and journal, this pocket-book contains much useful printed matter, including tables of the principal poisons and their antidotes, of fees legally claimable by medical men, a pharmacopœial companion, a table of eruptive fevers, and other information indispensable to the busy practitioner.—Pettitt's Diaries, published in over fifty different sizes and varieties (Griffith, Farran, and Co., Newbery House, London, and Sydney), include convenient descriptions for the office or pocket, and are published at extremely low prices.—We have also received from Mr. Henry Frowde, of the Oxford University Press Warehouse, samples of the "Finger" Prayer Book. This miniature book, containing 670 pages, weighs in limp binding about three-quarters of an ounce, and is only one inch in breadth, three inches and a half in length, and one-third of an inch in thickness. The volume is beautifully got up, and excellently printed on Oxford India paper. It is a pretty and curious example of the bookbinder's and printer's art; but we question whether we could advise the habitual use of such very small type, clear and legible though it be. An edition is also issued which omits the calendar and the occasional services, thus reducing the thickness by one-third, and bringing the weight to hardly more than half an ounce.—*The Law Almanack* for 1890 (published at 1, Warwick-court, Holborn) has been considerably enlarged, carefully revised, and corrected to date, and a new feature introduced—viz., historical and chronological information.

The Charities' Register and Digest, 1890. Third Edition. London: Longmans, Green, and Co.—This is a classified Register of Charities in or available for the metropolis, together with a digest of information respecting the legal, voluntary, and other means for the prevention and relief of distress, and the improvement of the condition of the poor. The work, which is elaborately indexed, contains an introduction by C. S. Loch, Esq., Secretary to the Council of the Charity Organisation Society, London. There is also an appendix containing full information as to benevolent institutions, friendly societies, trade societies, registry offices, and savings banks.

Blackie's Modern Cyclopædia (*Fir–Ilo*).—Vol. IV. of this useful series commences with the word "Fire," which is described briefly and clearly, together with its compounds, such as fire-brigade, fire-damp, &c., and ends with "Ilorin," an important trading town in the Western Soudan. The maps, illustrations, and portraits are numerous and excellent, whilst the information given under the various headings appears to be full and accurate.

New Inventions.

APPLIANCE FOR THE TREATMENT OF PROLAPSUS RECTI.

As relaxation of the lower bowel, leading to its extrusion and prolapse, is of very common occurrence, more especially in the young, and is attended with so much inconvenience, and, if neglected, by such untoward results, a means of obviating recurrent prolapse without undergoing an operation of any kind—nearly always so strenuously opposed by both parents and patients—should be accorded extended trial. I have almost always found that liquid, solid, or semi-solid applications *per se* were comparatively useless, having also the disadvantage of being more or less painful, and in some cases even producing evacuation followed by extrusion of bowel. The foregoing refers more particularly to prolapse resulting from costiveness, natural delicacy with straining, and threadworms. However, the appliance I have devised will, I believe, meet the requirements of every case, whether arising from vesical stone, urethral stricture, piles, prostatic and rectal disease, or the other causes before mentioned, by giving support when and where needed—viz., at the time of going to stool, and at the junction of skin and mucous membrane. I now append a brief description of my recto-perineal pad. It consists of a

Digitized by Google

strap, which is buckled round the waist, having an india-rubber band passing down between the legs from the middle of the back, where it is attached to the waistband. Before reaching the median raphe, this perineal band divides into two, and the ends are brought out in front and hooked up to the waistband on either side, permitting of any degree of tension or laxity, as they are provided with a regular series of holes. There is a sliding air pad or cushion, having a hole in its centre and provided with an easily dilatable flange surrounding the hole; the flange permits of the passage of fæces, but keeps the bowel in position. The pad can be removed at will for cleansing

FIG. 1.

FIG. 2.

purposes by simply unhooking the ends of the perineal band and sliding it off; it is kept in position by buttoning to the under surface of the rubber band. The mouthpiece of the inflating tube is covered with a reversible chamois bood, and lies comfortably in the hollow of the back. This appliance has the advantages of (1) facility and simplicity of application, (2) comfort in wear, (3) cleanliness, and (4) efficiency, and was made for me by Messrs. Arnold of West Smithfield. The woodcuts show it in position, and the pad separated from bands.

G. E. J. GREENE,
Medical Officer, Ferns District, County Wexford.

MODIFICATION OF O'DWYER'S INTRODUCER FOR INTUBATION.

THE instrument here figured was made for me by Messrs. Mayer and Meltzer, and its use has materially facilitated the operation of intubation, both to myself and others. The original instrument appeared to me to have the following drawbacks:—1. The spring claws for pushing off the tube into the larynx almost invariably failed in my hands, and, by projecting over the top, made it a difficult matter to push the tube home with the forefinger of the left hand. 2. When the tube had been oiled and placed on the pilot, it frequently slipped off just as it was being introduced into the larynx.

The modifications and advantages are as follows:—1. A small ring placed at the end of the stem on the right side. The string, having been threaded through the hole in the shoulder of the tube, is passed through the ring and held against the handle with the forefinger of the right hand. This effectually prevents the tube from slipping off the pilot, keeps the string close against the stem, and, being on the right side, does not interfere with the manipulations of the left hand. 2. The spring claws are dispensed with altogether, and the tube can readily and with certainty be pushed off the pilot, when introduced into the larynx, with the left forefinger. This makes the instrument a much cheaper one, and more easy to clean. This is an important point if there is only one set of instruments, which may have to be used both for cases of diphtheria and other emergencies.

W. H. C. STAVELEY.
Victoria Hospital, Chelsea, S.W.

THE DENTOILETTA, OR DENTAL TOILET MIRROR.

THIS is a simple and ingenious arrangement for enabling all persons to examine their own teeth. As will be seen from the illustration, it consists of a small hand mirror and a mouth mirror, both mounted on a ball-and-socket joints, and attached to the same handle, the distance

between the two mirrors being such that the light is focused upon the small one. It should be of value as directing attention to the teeth, and is not meant to supersede periodical professional examination. It is a well-made, handsome, and useful adjunct to the toilet table. The patentee is Mr. E. A. Tice, 12, Cumberland-park, Kensal-green, W.

THE DWELLINGS OF THE POOR.

A DEPUTATION from the Housing of the Working Classes Committee of the London County Council waited upon Mr. Matthews at the Home Office on Monday afternoon in connexion with the Acts bearing upon the subject of the dwellings of the poor. The deputation (which included amongst its members Dr. G. B. Longstaff and Mr. Shirley Murphy, medical officer of health to the London County Council) was introduced by Earl Compton, who said that the points which he had to put before the Home Secretary were five: (1) That the medical officer of the Council shall have equal authority with the local officer: or, failing that, (2) the Council should have the same powers of compulsory purchase as the existing Acts give in regard to obstructive dwellings; (3) that where premises are required to be purchased the owner should not have the option of retaining the site; (4) that the term "obstructive" should be defined in the Act of Parliament; and (5) that in lieu of the optional appeal to the High Court given by Section 9 of the Act of 1868 such optional appeal should be to the Local Government Board. He suggested that these amendments might be effected by a few short clauses introduced into a Bill.

The Home Secretary, in his reply, said that the Government hoped during the approaching session of Parliament to pass an Act consolidating the existing legislation regarding workmen's dwellings. He was afraid, however, that they would imperil the chance of its passing, and run a great risk of wrecking the whole thing, if they were to try to make it also an Amending Act, which by touching vested interests would be certain to provoke serious opposition from some quarter or another. The Government would give the whole matter their most careful consideration.

THE LANCET.

LONDON: SATURDAY, DECEMBER 21, 1889.

THE remarkable epidemic malady which is just now attracting so much attention is one of those diseases the records of which go far back in the history of medicine, and yet it is one concerning which there is a singular lack of precise knowledge. Not, indeed, as regards the mode of its occurrence and spread, for literature abounds in careful and complete descriptions by many trustworthy observers[1] nor yet as regards its symptomatology and its course, for here, too, there is ample material supplied by the physicians of the past. But it is as to its nature, its etiology, that we are so much in the dark—just in that field, in fact, in which the science of the nineteenth century has made so much advance with respect to disease in general. In its mode of diffusion influenza, in more than one feature, stands almost alone among epidemic diseases. In the first place, it spreads with remarkable rapidity once it is established in a centre—as witness the recent accounts of its progress in St. Petersburg, Vienna, and Berlin. Secondly, it tends more or less rapidly to become pandemic, for although minor and comparatively limited outbreaks are often recorded, yet its liability to diffusion over whole continents, and indeed from one hemisphere to the other, is one of the best-known facts concerning it. The disease has therefore no geographical limitation; it is apparently uninfluenced by season or climate, and its virus travels over sea and land in a manner so baffling and contradictory to the ordinary conceptions of the transmission of infection as to render any simple explanation of its nature almost impossible. It has been compared with cholera in the manner of its diffusion; but the analogy is by no means exact, for influenza, unlike cholera, is not apparently confined to the lines of human intercourse, although there are not wanting some who claim both for cholera and influenza a propagation by contagion. But in the case of influenza, the rapidity with which a whole population may be smitten appears to exclude contagion, which otherwise would seem so obvious an explanation of its spread; and a further point in disproof of this is the almost simultaneous outbreak of the epidemic at different parts of the same country. It is not surprising, therefore, to read of telluric and atmospheric influences as being accountable for the pandemic spread of influenza; yet it is clear that such a view is purely hypothetical. Influenza has not yet been studied in respect to its etiology so profoundly as have many other epidemic diseases. There is, for instance, hardly any record of bacteriological research into this disease, owing partly to the difficulties of such an inquiry, but mainly perhaps to the fact that well-marked and widespread outbreaks have not occurred within recent years. There are not many physicians now in London who had to deal personally with the great epidemic of 1847–48, of which the late Dr. PRACOCK has left us so interesting a study; and since that time no notable outbreak has occurred in this country. And here we would remark that there is, and from the nature of the case must necessarily be, some difficulty in identifying influenza. There are epidemic and seasonal catarrhs, with which the English people are specially afflicted, which are often termed "influenza," which seem to be contagious, and which, indeed, run a course similar to, if less severe than, the affection that is now engaging attention. Yet there are essential differences between cases of the one class and those of the other—differences in the severity of fever, the occurrence of complications, the mortality, as well as in the main fact of all—viz., the wide distribution of influenza proper to which we have just alluded.

It is more than probable that we shall be visited by this epidemic. *Already* we hear of an unusual prevalence of catarrh in the metropolis; but, in view of the season, one must be cautious in admitting that the disease which has made so many victims on the Continent has really arrived here. When it does come it will speedily make its presence felt, and the difference between an ordinary or even an unusual prevalence of catarrh and of true epidemic influenza will be soon appreciated. The population of London has more than doubled itself since 1847, when it was calculated that at least a quarter of a million were attacked by the complaint; so if it really comes we may expect colossal figures and an epidemic which will "beat the record" in that respect. Let us hope, however, that its type will be mild; for, although in proportion to other epidemic diseases, the mortality from influenza is very low (2 per cent. or less), yet experience shows that to the very young and the aged, to the debilitated from disease or impoverishment, its effects are, directly or indirectly, very serious. In 1847 the mortality in London during the prevalence of the epidemic rose in proportion to the previous mortality in the observed districts. Our want of complete knowledge of the nature of the disease renders it difficult to suggest measures of prophylaxis other than the uniform observance of general hygienic rules. The treatment of the attack itself, marked as it is by high fever, catarrh of the respiratory and gastro-intestinal tracts, must be mainly restorative, directed to the relief of symptoms. The use of quinine will doubtless be largely replaced by antipyrin and antifebrin, which are reported as having been freely prescribed in Berlin with benefit. The opportunity for exact clinical records which may arise will, we trust, be largely embraced, and thus our knowledge of one of the most interesting affections to which mankind is liable be materially increased. In the matter of thermometric observation alone there is ample scope for enriching literature with interesting studies. Should we be visited by the disease, we doubt not that full advantage will be taken by the practitioners of this country of the ample material that will fall to them; and we would further suggest, in the interests of scientific medicine, that, as nearly half a century has elapsed since the last outbreak of the disease in England, no means should be left untried to

[1] M. Ch. Eloy, in Rev. Gén. de Clin. et Therap. (Dec. 1889), points out that the recorded epidemics increase with the progress of the centuries—viz., from 1 in the eleventh century to 41 (now 46) in the nineteenth. But this is hardly more than can be expected, with growth of literature, for there are countries—e.g., France—where the disease is singularly frequent in its recurrences. It is the pandemics which are seemingly rarer than they used to be.

Digitized by Google

ensure a full record of the occurrence of cases if it should again appear in an epidemic form in the British isles.[2]

THE extreme difficulty and the urgent importance of a definite diagnosis of phthisis at the earliest possible period are universally acknowledged. Both with a view to either calming or confirming the patient's fears, and of insisting upon such an alteration of the mode of life and such remedial measures as offer the best prospect of arresting the tubercular process, an early and confident diagnosis is eminently desirable. Hence Dr. HARRIS'S recent contribution to the subject in our columns has no doubt received the careful attention of our readers. On some of his points there will be general agreement. That a history of hæmoptysis, especially of repeated slight hæmorrhages, is of great significance no one will question. If we can certainly exclude the spurious forms of hæmoptysis, such as those from the gums and pharynx, and if the patient be not a "bleeder," the fact that he has repeatedly spat blood raises a very strong presumption that he is the subject of tuberculosis. That family history is also very important most authorities, in this country at least, will allow. There is at present a tendency among continental writers, who are usually adherents of the bacillary and contagionist view of phthisis, to minimise the hereditary factor in its causation; but this is probably only a temporary swing of the pendulum, the clinical evidence that phthisis is strongly transmitted being apparently irrefragable.

It is when we come to define the earliest positive physical signs of phthisis that we find it difficult to lay down any rules that do not admit of large exceptions. Dr. HARRIS attaches weight to impaired movement at one or both apices, and no doubt when present this is very important. It may be best recognised, not by simple inspection, but by the examiner standing behind the patient, placing his hands upon the sub-clavicular region of each side, and noting whether both sides rise equally and readily during inspiration, or whether there is, as it were, a delayed rise on one side. Dr. HARRIS points out another sign which, he says, has not received in this country the attention which it deserves. This sign is the lower limit of pulmonary resonance in the supra-clavicular and supra-scapular regions on the affected, as compared with the sound, side, which may be detected in cases where no dulness is present. This sign may, however, be obliterated by the presence of emphysema in the neighbourhood of the diseased patch of lung. Any dulness or tonelessness on percussion at one apex must, in a doubtful case, be regarded as of great significance.

The auscultatory signs present at a very early stage of phthisis offer great variety, and need a very careful estimate to determine their true significance. In some cases where, on general grounds, the diagnosis of phthisis seems practically certain, the most careful and diligent auscultation fails to detect any abnormality. This is by no means so surprising as at first sight it appears to be. We know that it is not very rare for all auscultatory signs to be absent during the first two or three days of pneumonia, although we feel certain that consolidation is going on. This is very probably explained by the hypothesis that in such cases the process is deep-seated in the lung, and that the sounds produced by the consolidation are masked by the normal vesicular murmur. In like manner, early phthisis may be attended by a scanty deposit of tubercles, not sufficiently superficial to produce auscultatory signs which can be heard above the normal breath sounds.

Great importance must be attached to the character of the breathing in these cases. If the vesicular murmur be feeble, or somewhat harsh or bronchial in quality, or if expiration be much prolonged, we are justified, in the absence of any other cause adequate to produce these signs, in regarding them as probably tubercular in origin. It is of the first importance, however, to make certain that these signs are present, either solely, or at least in a more marked degree, on one side. The puerile breathing of children and the somewhat bronchial breathing normally present under the right clavicle are fruitful sources of error with beginners. Dr. HARRIS utters a caution against relying too much upon prolonged expiration, if no other sign be present; and no doubt it is insufficient of itself to warrant any safe inference. That peculiar form of interrupted breathing, called by French writers *respiration saccadée*, was formerly generally relied upon as a sign of some value in early phthisis, but probably most authorities will now admit that this phenomenon is often of neuro-muscular origin, and cannot therefore be depended upon to give us any satisfactory indications of the condition of the lungs.

Adventitious sounds form the last group of the physical signs of early phthisis. There can be no doubt that they vary much from day to day, which is not surprising when we reflect that they owe their origin to the varying degree of bronchial catarrh present in the neighbourhood of the tubercular deposit. The supra-scapular region should be as carefully investigated as the sub-clavicular, as many observers are of opinion that it is on the average the earliest seat of the deposit. The most characteristic adventitious sign of the earliest stage is the presence of a few dry crepitations, which do not disappear on taking deep breaths and are rather accentuated by coughing. There are cases, however, in which the earliest adventitious sign is a musical râle or rhonchus, identical acoustically with that heard in bronchitis, but deriving its grave significance from its distribution. Pleuritic friction may also be one of the earliest signs of phthisis, and if apical in distribution should excite our suspicion. As regards the diagnostic value of the presence of the bacillus in the sputum, we are in this position. Its presence is pathognomonic of tubercle, but failure to find it is of very little value, as the bacilli may be few in number and may escape detection, even at the hands of a careful observer.

On the whole, while the ear diagnosis of phthisis is admittedly difficult, few mistakes will be made by the practitioner who balances signs, symptoms, and history (personal and family) carefully and guardedly, and who does not allow himself to be led astray by any single indication

[2] One of the best accounts of influenza is that by the late Dr. Parkes in Reynolds' Syst. Med., vol. i., 1870. See also Wilson; Pepper's Syst. Med., vol. i., 1885; Biermer; Virchow's Handbuch, v., 1854; Dr. Peacock, "Influenza," 1848; and Quain's Dictionary. The history of the disease down to quite recent periods is to be found in Hirsch's Hist. and Geog. Pathology (New Syd. Soc. Trans.), vol. i.

Digitized by Google

Needless to say, finally, the use of the thermometer is imperative, and may serve to clear up many doubtful cases.

A CHARGE of libel was tried on Dec. 3rd in the Queen's Bench Division, before Mr. Justice CAVE and a special jury. The plaintiff was Mr. WILLIAM INGLIS MASON, L.R.C.P. Ed., M.R.C.S. Eng., of Sudbury, Suffolk, and the defendant was Mr. CHARLES HENRY CHEVENS, proprietor and conductor of the *South-West Suffolk Echo*. Sudbury is a borough with a population of some 6580 people; and Mr. MASON, succeeding his father (who practised for about fifty years), has himself practised there for about twenty years—a pretty fair record of father and son, involving that element of continuity and permanence which is always a presumption of honest work and character. The *South-West Suffolk Echo*, owned and conducted by Mr. CHEVENS, has had an existence of about eighteen months. Mr. LOCKWOOD and Mr. LAWSON WALTON were retained for the plaintiff, and the Solicitor-General, Sir EDWARD CLARKE, Q.C., M.P., for the defendant. The report of the proceedings occupies nine columns of small type of the *Suffolk and Essex Free Press*, which will be some excuse for a slight delay on our part in commenting on the case. We are, however, grateful to our contemporary for a very admirable report, involving questions and judgments of great interest to the profession and the public. There were three libels complained of by Mr. MASON; but two completely broke down, and we shall describe briefly only the chief one, which was after this manner. On Jan. 6th, 1889, a Sunday morning, a woman named SUSANNAH SHARMAN came to Mr. MASON'S surgery and asked him to visit her child. He was parish surgeon for Sudbury, as well as a private practitioner with a large club connexion, as we shall presently see. He asked her if she had a parish order. She replied, "No." He then said, "You must procure me a parish order or pay me the usual fee of 5*s*." The relieving officer lived two miles off. On the woman raising this objection, he explained that the relieving officer would be at the neighbouring church at half-past ten, and that, if he wished it, he would attend the case. He explained to the Court the alternative method by which the woman was to pay 5*s*. In his father's time a great Sick Fund was formed to meet the case of those who did not wish to be attended as paupers. To adults in health the charge was 1*s*. a quarter, to children 6*d*. a quarter. This fund has in the town and surrounding district a membership of about 10,000, but the remuneration is estimated at £250. The woman left and did not return till the following day, only to announce the death of the child and ask for a certificate, which Mr. MASON, of course, refused, referring the parent to the superintendent of police, with a view to an inquest, at which Mr. MASON gave evidence, and the jury returned a verdict of "Death from natural causes." On Jan. 12th, the *South-West Suffolk Echo* came down heavily on Mr. MASON, and declared "that such heartless conduct as his could hardly be capped," &c., and expressing surprise that the jury and coroner did not pass a vote of censure on the doctor for "such parsimonious, such heartless conduct." This is very fine writing for a young journalist living at a distance from Sudbury, at the expense of a man who had a local habitation and a name there such as we have described, and whom the journalist did not know. On the 19th the *South-West Suffolk Echo* had another libellous article and several little echoes in this style: "Was there ever a more flagrant instance of tutored barbarity before recorded?" &c. We cannot unfortunately give all the particulars of this case, in which many questions of much interest were raised as to the necessity for an order before a Poor-law medical officer was compelled to attend. The woman denied that Mr. MASON had told her that she could see the relieving officer at the church on the morning in question. But Mr. MASON was confirmed in this by his assistant. He further gave his reasons for doubting the fitness of the woman for parish relief—viz., that she was a weaver, and living with a man both at work and in receipt of a pension. The relieving officer, in his evidence, said that he would not have assumed the responsibility of giving an order to people in the position of the applicants, who said they had not a penny, but who were shown to have received, with the pension, within a short time of the period of application, £3 10*s*. The judge distinctly laid down that a doctor could not be burdened with the duty of deciding who was a pauper, saying that the relieving officer was much more fitted to do so. He also expressed himself strongly in favour of the sick fund, and argued that the large membership showed how much it was appreciated. He very strongly laid down that journalists who published newspapers for their own pecuniary benefit had no privileges of censure or criticism which did not belong to the people. The jury gave a verdict for the plaintiff, with damages for £20. We heartily congratulate Mr. MASON on the result of this most proper action of his. Medical men are the easy targets for those who write sublime articles in ignorance of the facts of medical life and labour, and it is very gratifying to see judges and juries agreed in vindicating, as in this case, the conduct and the character of members of the profession.

THE details of the new scheme for reforming the University of London have been forwarded from the Senate to University and King's Colleges, the Royal Colleges of Physicians and Surgeons, the Council of Legal Education, and the Incorporated Law Society, but we cannot see how they can be fully considered and reported on by these bodies before the meeting of Convocation in January next. They have already been referred to the Committee of Delegates of the Royal College of Surgeons and to special committees by some of the other bodies. The constitution of the Senate follows in the main the lines laid down by the Royal Commissioners, and it is only in the definition of constituent colleges that the first serious departure from their recommendations is to be found. The Commissioners say that constituent colleges should be such colleges as University College and King's College, which give academical instruction upon a complete system and an adequate scale in all the faculties, whilst institutions limited to the studies of a single faculty may be "associated" with the University in respect of that faculty, but they should not be called "constituent colleges." As the faculties are to consist of representatives of constituent colleges, and are, in each faculty of Arts, Laws, Science, and Medicine, to elect three members of the Senate, as well as members of a Board of Studies, and to advise on the admission of any

Digitized by Google

constituent college, it is obvious that great importance will be attached to the precise definition of a constituent college. This is much widened in the proposed new scheme of the Senate of the University, by including institutions in or near London which not only give academical instruction upon a complete system and an adequate scale in all the faculties, but those which give instruction upon an adequate scale in one or more, even though not in all, the faculties. Every metropolitan institution formerly affiliated to the University of London will thus be brought into the rank of constituent colleges, and this altogether alters the character of the Commissioners' suggestions. We question if the constituent colleges will be satisfied with such modifications in the examinations as are proposed in the following clause, which is the only concession to those who ask for an insistence on regular attendance at a course of systematic lectures and systematic practical training: Matriculated students may be admitted, without passing the matriculation examination of the University, from among such students of the constituent colleges as have completed their eighteenth year, and who shall produce evidence satisfactory to the Senate of their diligent attendance during an academical year in a constituent college at lectures on the general subjects of the matriculation examination, or such of these subjects as the Senate may from time to time appoint, and of their proficiency in the general subjects of the said examination, as tested by examination within the said constituent college. The extra-metropolitan institutions are to have no voice in the management, but their students are to be admitted to similar privileges as those from constituent colleges. The professional clauses are the following:—"To accept, in lieu of the passing of the preliminary scientific examination in medicine, certificates that the students have passed at the Royal Colleges examinations which are to the satisfaction of the Senate a sufficient test of competent knowledge in the subjects of the said preliminary scientific examination.—In the event of the establishment of a second examination for the degree of M.D. not requiring the attainment of so high a standard as the present examination, to confer on all existing M.D.'s of the University, and all who may hereafter pass the examination which will require the attainment of the higher standard, the right to describe themselves as M.D. with honours (M.D. Lond. honours), and on all existing M.B.'s the degree of M.D." Honorary degrees may be conferred, and professorships and lectureships, whether attached or not to any particular college, may be established. We doubt whether these concessions will be sufficient for the teaching colleges, and the last paragraph, although suggested by the Royal Commissioners, will lead to considerable friction and heart-burning among existing graduates. As it is almost impossible for the Senate to declare themselves satisfied with the present examination in Physics and Chemistry at the Conjoint Examining Board, considering their own excessively high standard at present in these subjects, that clause must be looked on as practically inoperative.

WE regret to hear that Professor Bergmann is suffering from pneumonia, contracted apparently in going to Halle to attend Professor Volkmann's funeral.

Annotations.

"Ne quid nimis."

HOSPITAL MONOPOLIES FOR CERTAIN QUALIFICATIONS.

IT seems not a little inconsistent that, while we are blaming France, Switzerland, and other countries for being ungenerous in the recognition of British diplomas, we have monopolies for certain hospital appointments in our own country in favour of certain colleges. It is felt to be a hardship by Bachelors of Medicine of the Universities of Scotland and Ireland, Licentiates of the Royal College of Physicians of Edinburgh, as well as by Fellows, Members, or Licentiates of the King and Queen's College of Physicians in Ireland, that they are not eligible to the office of physician in many English hospitals, and, similarly, that Licentiates in Surgery of the Scottish and Irish Colleges of Surgeons are, in many hospitals, not eligible to the office of surgeon, as Fellows or Members of the Royal College of Surgeons of England are. This question has often been discussed of late, and within the last few weeks has been recpened at Derby with reference to the rules relating to the qualification of physicians and surgeons in the Derbyshire General Infirmary. The present rules have the exclusive effect above indicated, and at the annual meeting of the governors it was sought, on the motion of Dr. Murray Lindsay, to revise the rules and give them a more liberal form. But the attempt failed completely, under the influence of certainly some very loose statements, such as the following by Mr. E. C. Green, ophthalmic surgeon and junior member of the staff, who explained to his audience that students could go to Edinburgh and get a University degree very easily. This is certainly inaccurate and undesirable language in one holding the three ordinary English qualifications. We do not mean to endorse all the reasoning by which Dr. Murray Lindsay argued for a broader recognition of diplomas—as, e.g., where he maintained that the larger proportion of rejections at the examination for the licences of Edinburgh College showed a severer examination than in the London College. The proportion of rejections is no criterion apart from other proofs of the standard of examinations, and it has long been known that at some of the lowest examinations there was the highest proportion of rejections. The fact is that we want accurate and impartial information on the equivalence of corresponding examinations. We are of opinion that all mere territorial distinctions of medical qualification for high office in public institutions are unseemly and inconsistent alike with the Medical Act and the spirit of the age. Still it is not right to forget that until at least a very recent period similar qualifications in different divisions of the kingdom did mean very different degrees of education. For example, the Fellowship of certain Scottish colleges, if not Irish ones, could practically be obtained without examination. This we believe is no longer the case. But we are still without any impartial and judicial report as to the comparative strictness of the respective examinations for the Fellowship—say, of the English, Scottish, and Irish Colleges. Until this is forthcoming it is vain to expect a complete admission of the equivalence of what ought to be corresponding qualifications. All that the Inspectors of the General Medical Council have to ascertain, even as regards the highest examinations, is that they are a test of bare competence to practise. Much more than this is wanted for the high posts of the profession, and the Scotch and Irish Colleges will best contribute to a liberal recognition of their Fellowships and qualifications by demonstrating the equivalence of the examinations by

Digitized by Google

which they are gained to those passed by the candidates for corresponding qualifications in England. If this were done, the mere territorial distinctions of qualification could not last a day.

A NEW SOURCE OF HYOSCYAMINE.

A RHIZOME which has recently been offered in the drug market as a substitute for belladonna root under the name of "belladonna scopolia" has been very fully investigated in the research laboratory of the Pharmaceutical Society. At the last meeting of the Pharmaceutical Society Professor Dunstan communicated the results of a chemical examination of the drug, which shows that it contains ·5 per cent. of hyoscyamine. With the possible exception of a mere trace of hyoscine, no other mydriatic alkaloid was found in the plant, which would seem by this circumstance to be distinguished from other plants belonging to the same natural order—viz., belladonna, hyoscyamus, stramonium, &c.—from which different proportions of atropine or hyoscine are present in addition to hyoscyamine. Professor Dunstan points out, however, that this difference may possibly be due to the methods employed by previous workers in extracting the alkaloids from these plants, which may have led to the decomposition of the hyoscyamine by heat or by fixed alkalies. Among the other compounds isolated from the new drug were a crystalline sugar resembling dextrose, a fluorescent substance, and cholesterin. The latter substance is present to the extent of ·1 per cent., and it was subsequently found to be contained in the root of Atropa belladonna. The resemblance between the two plants is borne out by a comparison of the structures of the roots which has been made by Mr. Greenish. The rhizome was referred to Mr. Holmes for identification, and he states that it is derived from Scopola carniolica, a plant which grows, apparently abundantly, in Austro-Hungary and in other parts of Europe. The pharmacy of the drug is fully described in a paper by Mr. Ransom. The therapeutic action of preparations made from the rhizome was the subject of a communication from Sir Dyce Duckworth, who shows that the drug may be used with success as a substitute for belladonna, apparently with the advantage that it does not give rise to the dryness of the throat which is produced by belladonna. Further trials of its therapeutic action are being made. Since Scopola carniolica contains more alkaloid than belladonna, is easily obtainable, and is at present cheaper than that drug, and, moreover, furnishes a valuable source of hyoscyamine, it is probable that more will be heard of its employment in medicine. The papers to which we have referred are printed in the *Pharmaceutical Journal* of Dec. 14th.

THE HIGH DEATH-RATE IN NEWCASTLE-UPON-TYNE.

AN influential deputation, representing the clergy, ministers, and ratepayers of Newcastle-upon-Tyne, was received by the Mayor and City Council at a meeting held on the afternoon of the 4th inst., when a memorial was presented requesting the serious consideration of the Council for the abnormally high death-rate that has recently prevailed in the city. In the memorial especial attention was directed to the fact that the causes of the high death-rate in Newcastle were fully set out in the special report of the medical officer of health presented in 1883, but that since that date comparatively little has been done to remove the most serious of the sanitary defects to which the high death-rate was therein referred. The memorial avers that the drainage and sewerage of the town are still undoubtedly defective; that slaughterhouses, cowhouses, and cattle fairs exist in close proximity to dwelling-houses; that the city still contains 20,000 middens; that many of the dwellings are quite unfit for habitation, being indeed mere "fever dens"; that the water-supply to tenement property is very insufficient; and that serious overcrowding is permitted in dwellings. Such is the indictment against the sanitary condition of the city contained in the memorial signed by upwards of fifty of the clergy and ministers of the city, and presented to the Mayor by the recent deputation. Whatever may be the degree of justification for so sweeping a condemnation of the health condition of the city, the presentation of such a memorial should materially strengthen the hands of the sanitary authority in carrying out the radical reforms which undoubtedly appear to be necessary. The unfailing key to the health condition of all urban aggregations is the improvement of the house accommodation of the poorer of the working classes, and, after due allowance for possible exaggeration, there can be no question that this is a subject demanding the earnest attention of the sanitary authority of Newcastle-upon-Tyne. Much has been said, with regard to the recent high death-rate of this city, respecting a possible under-estimate of its population, upon which the death-rate is calculated. Judged by the birth-rate, such an under-estimate, especially during the years 1886–7, appeared probable; but it must be borne in mind that the annual number of registered births in the city during the four years 1886–9 has been practically stationary, while the population is estimated to have increased at the rate of 2000 per annum. It follows, therefore, that if the population was under-estimated a few years ago, such under-estimate has now decreased, if it has not disappeared. Moreover, any idea that the high death-rate in the present year is to any considerable extent explained by such under-estimate of the population may at once be dismissed as fallacious. Putting the population question entirely aside, the undue proportion of the deaths due to the principal zymotic diseases and the terribly high rate of infant mortality afford conclusive evidence of insanitary condition, justifying the action of the memorialists at the recent deputation to the Corporation of Newcastle-upon-Tyne as the sanitary authority of the city. The memorial was referred to the Sanitary Committee of the Council for consideration and report, the result of which will be anxiously awaited by all who have the welfare of the city at heart. We are glad to observe that the action of the deputation is already bearing fruit, as at the last meeting of the vestry an animated debate took place upon a resolution in favour of a rigid inquiry being made into the sanitary condition of the city, the discussion being eventually adjourned for a fortnight.

A SIXPENNY INFIRMARY!

THE medical profession in Bradford is considerably agitated at present by the extraordinary proposal to convert the infirmary of that town into a great sixpenny dispensary, without the essential condition of such institutions, that the medical attendants should be paid for their services. The proposal is all the more surprising and painful in that it has emanated from one member of the medical staff. In brief, his proposition is that every patient in the out-patient department shall pay sixpence per visit for advice and medicine. Even assuming that the object in view is to diminish the evil of an excessive attendance in that department, and that the means proposed would be successful, it must appear evident to everyone that the end does not justify the means. The co-operative principle, whereby a number of persons, under proper regulations, by small individual contributions make up a sufficiency to pay for medical attendance for the contributors, is one which must meet with general approval. But that the skilled professional services of the infirmary staff at

Digitized by Google

Bradford should be gratuitously dispensed for sixpence a visit (as the staff would receive no pay), including medicine, bears no resemblance to co-operation. We understand that the members of the profession in Bradford have already held a preliminary meeting, at which an opinion strongly adverse to the proposal was unanimously expressed, and it has been arranged to summon a general meeting of the whole profession in the town and neighbourhood to discuss and, it is to be hoped, give the *coup de grâce* to any such proposal. The fact that the board of the infirmary is exceeding its income is no justification for such a course, especially when there have long been loud complaints that the excessive expenditure is in directions which are not charitable, which unfairly tax the honorary staff, and are objected to by the general practitioner as offering unfair inducements to persons who can pay for private medical attendants to become recipients of gratuitous medical relief at the infirmary.

THE TREATMENT OF INFLUENZA.

M. H. HUCHARD, writing in the *Revue Gén. de Clin. et de Thérap.* (Dec. 12th), speaks of nervous prostration as being a chief clinical characteristic of severe cases of influenza, requiring for its treatment quinine, alcohol, and, in bad cases, even injections of caffein and ether. Quinine, he says, is indicated on account of the markedly remittent type of fever, and to moderate the evening exacerbation it suffices to give a full dose (5 to 15 grains) of the sulphate or hydrobromate in the morning. Smaller doses more frequently taken are useful for their tonic rather than antipyretic effect. In the neuralgic or rheumatoid form of influenza antipyrin (15 grains) combined with bicarbonate of soda (7½ grains) is recommended by M. Huchard, to be taken every four hours, or instead of antipyrin, phenacetin or salol (7 grains). Influenza often assumes a broncho-pulmonary form, and in certain cases is very grave. In the epidemic of "la grippe" in 1886, recorded by M. Menetrier, the pneumonic forms were very asthenic. In such cases, tonics, milk, alcohol, and, in fact, general restorative measures are indicated rather than local applications to the chest. If the dyspnœa became severe, and the condition termed by Graves "pulmonary paralysis" ensues, then strychnia is of value; or in case of impending asphyxia or renal asthma, venesection; but when the asthenia itself threatens life, there should be no hesitation at resorting to hypodermic injections of ether, and especially of caffein. For the gastro-intestinal form, mild aperients, ipecacuanha, and the use of salicylates of bismuth or of magnesia, naphthol, or iodoform to promote intestinal antisepsis, are indicated.

BOXING THE EARS AND ITS RESULTS.

WE would fain hope that, in deference to repeated warnings from various quarters, the injurious practice of boxing the ears, once common in schools, is fast and surely becoming obsolete. It is too much to say that this desirable end has yet been realised. Certainly the recent observations of Mr. W. H. R. Stewart do not give colour to any such view. In a pamphlet on "Boxing the Ears and its Results," lately published, and illustrated by appropriate cases, he briefly summarises his own experience in the matter. He reminds us that, notwithstanding the toughness of the aural drumhead, its tense expanse will rupture only too readily under the sudden impact of air driven inward along the meatus, as it is in the act of cuffing; and he shows that in one instance at least this injury resulted from a very slight though sudden blow. Given early and skilled attention the wound may heal very kindly, but if the beginning of mischief be overlooked, as it often has been, further signs of inflammation soon follow, and a deaf and suppurating tympanum is the usual result. There is practical wisdom in the statement that this consequence most readily follows in the case of the poorly developed and underfed children who abound in every Board school. In them an earache would probably receive no very strict attention, and disease might for a time work havoc unimpeded. Where chronic suppuration exists already, and it is only too common, a random knock on the ear may result, as in a case related in THE LANCET in a fresh otitis, with fatal brain complications. Schoolmasters and others, who may at times be tempted to apply the correcting hand somewhat too carelessly, might read the few pages of this little work with equal interest and advantage. The close connexion between ear and brain should never be forgotten, and the reflection that injury to the former organ most easily terminates in total deafness, and in suppuration which may any day take a fatal course, should assist in the preservation of a sometimes difficult patience.

THE LATE SURGEON-MAJOR SHIRLEY DEAKIN.

WE regret to learn of the death of Surgeon-Major Shirley Deakin of the Bengal Army, which took place at Jhelum from enteric fever. He was well-known as an energetic and enlightened surgeon, and had been editor of the *Indian Medical Journal* since its foundation. A correspondent writes:—"I heard with much pain last week of the death from typhoid of my old college friend Shirley Deakin at the early age of forty years. I have a vivid recollection of him as a student of University College between the years 1867 and 1871, for he was then marked out from his fellows for liberality in thinking, enthusiasm for humanity, and frank outspokenness. Shirley Deakin's was a fine character, chivalrous almost to a fault, and keen to redress injustice. Many of his fellow students may recall the prominent part he took in the meetings of the College Medical Society, and the interest he showed in social questions. He was a warm advocate of legislation for contagious diseases—an advocacy based as much on the cause of the unfortunate victims of vice as on grounds of political economy,—and he read a paper on the subject before the Society, in which he proved how thoroughly he had mastered all its bearings. On leaving college he held for a year or two the office of house surgeon to the Male Lock Hospital, and about 1875 entered the Indian Medical Service. Since then he has paid a few visits to his mother country, but he threw himself into the duties of his office with the same energy that characterised him in old days. His old friends have noted with pleasure how in the midst of officialism Shirley Deakin has continued to champion the cause of the oppressed and to denounce injustice and wrong. Nor did he neglect the pursuit of scientific medicine, often contributing papers to the Indian and home medical journals. Indeed, I think that he was the chief promoter of a journal which he edited. I must, however, leave to others who are better acquainted with his Indian career to speak of his work there. I am sure that none who knew him can think without sorrow of the premature close of a useful life."

ENGLISH PRACTITIONERS IN FRANCE.

THE *Nice Gazette* makes a very lame attempt to justify the illiberal action of the French Government in refusing to grant permission to English medical men to practise in places resorted to by the English. It states that, a French examination having to be passed, English residents may feel sure of the competence of those who henceforth seek to practise there. This is a poor compliment to English examining bodies, and not an argument likely to weigh with English people, who will certainly be apt to try home resorts more freely.

CAUSE OF DEATH FROM ELECTRIC DISCHARGE.

THE deaths which have recently occurred in New York from electric discharge, and the post-mortem examinations made on those fatally stricken, have led to the conclusion that in the course of the electric current through the body the blood is the chief conductor. This is precisely what has been known in this country since the year 1869, when Dr. B. W. Richardson conducted his series of experiments on death by electric shock with the large electric coil set up by Mr. Apps at the Royal Polytechnic Institution. In those researches the experimenter, by passing electric currents of high tension through sets of glass tubes charged with different conducting animal substances, made the fact demonstrable that of all the animal structures blood was, preferentially, by far the best conductor. In the same researches it was also demonstrated (*a*) that discharges which by their intensity kill most rapidly leave least mark of distortion or of external injury; (*b*) that on complete prostration from the shock the heart may continue in action for several minutes after what appears to be actual death; (*c*) that the injuries inflicted on a living body by the shock are superficial burns and ecchymosed spots on the outer surface of the body, darkening of the colour of the blood within the body, congestion of the heart and venous system generally, and injection, in some instances, of the mucous surface of the alimentary canal. The conclusion arrived at from these observations in regard to the cause of death from the electric shock was that the cause is a sudden expansion of the gases of the blood, with liberation of free gases from instant decomposition of the blood and the other fluids. Under the tension produced from the internal gaseous pressure, distension occurred in the venous canals, and the escape of bubbles of gas from the cavity of the cranium, on laying it open, was a frequent phenomenon. In one instance the right side of the heart of a sheep was ruptured from the cause named on the administration of the shock. But it was also observed in other instances that the whole of the discharge seemed to be conducted solely by the external surface of the body, under which condition there was extreme shock and prostration without death. It was this last observation that led Dr. Richardson to discard the idea of utilising the electric shock for the painless extinction of the lives of the inferior animals, and to substitute the lethal chamber for that humane purpose.

ROARING IN HORSES.

WE have received a copy of the "Report of a Committee appointed by the Midland Counties Veterinary Medical Association to examine and report on three horses operated on for roaring by the intra-laryngeal operation on May 24th by Professor Axe." The committee, consisting of one Fellow and four Members of the Royal College of Veterinary Surgeons, reports that in none of the cases did any benefit follow the operation; on the contrary, in its opinion, "the animals exhibit more distress under exertion than do roarers of about the same degree under ordinary circumstances." There is an important omission in the report: the date of operation is stated to have been May 24th, but no indication is given of the date on which the committee examined the horses. Time, however, is an important element in judging the effect of the operation. But the most remarkable thing connected with the report is the reason assigned for its publication. "The public have been led to form such sanguine anticipations of the success of these experiments that it is right they should know they are not always successful or unattended with risk." We are not aware that it has ever been stated that the operation is likely to be always successful. On the contrary, Dr. Fleming, in his last report on the Army Veterinary Department, states that of fifty-nine horses operated on, thirty-eight were cured, nine improved, and twelve not improved. We do not know of any other statistics of the operation having been published. These, so far as they go, certainly do not justify the expectation of the public as enunciated by the Midlands Association, but they show an amount of success which cannot be gainsaid by the failure of three cases. What is required for the elucidation of the subject is a report of all the cases—not merely the successful or the unsuccessful—when a sufficient period has elapsed after the operation to permit of an accurate opinion being formed of its results. We trust that in his next annual report Dr. Fleming will be able to give the statistics of a sufficient number to justify at least an approximate estimate of its value being formed, as in his last report he noticed a considerable number of cases in which more time was required before arriving at a definite conclusion as to the benefit derived. We cannot compliment the Association on the course it has adopted in publishing a report framed on so very unsatisfactory a basis as the results of only three cases.

A MORSEL OF CHRISTMAS LITERATURE.

WITHIN a few days most of our readers may hope to enjoy a time at least of partial relaxation from the daily round and task. Already the season's literary flood flows towards them with its varied contributions. Among such we may here mention one which those interested in folk-lore will read with pleasure. This is a short paper by Dr. W. Northrup in *Scribner's Magazine* for the current month on "The Pardon of Ste. Anne d'Auray." This article, as its name indicates, is occupied with a description of the chief religious festival of Brittany. Other sketches illustrate the customs observed on similar occasions in Finisterre and elsewhere. One and all they exhibit the native Breton in a light at once critical and appreciative. He is, according to the author, laborious, thrifty, and steady, but withal devout overmuch, and not very intelligently so. Of Druid-revering ancestry, he remains, with a change of instruction and of teachers, a born and loyal pagan, sanctioning a reference to rocking stones for the cure of sterility, and to holy water and Ste. Anne for other healing virtues. Notwithstanding the rites of shrines and holy seasons, however, he retains a Celtic shrewdness in matters of worldly profit, and naturally enough contrives to combine with his "duties" quite enough of the festival spirit and practice to make his high days yield their due of profit and enjoyment. A fluent style, careful description lightened by frequent incidents of travel, and, as usual in this magazine, an abundance of excellent illustrations combine to render Dr. Northrup's contribution to Christmas literature as interesting as it is instructive.

VOLVULUS AND ITS TREATMENT.

THE following conclusions are arrived at by Dr. N. Senn at the close of an interesting paper upon the Surgical Treatment of Volvulus (*Medical News*, Nov. 30), in the course of which he deprecates the resort to any such attempts at taxis as those advised by Mr. Hutchinson, and recently published in his "Archives of Surgery." Dr. Senn gives a successful case of volvulus of the sigmoid treated by laparotomy: "1. The predisposing causes of volvulus are either congenital or acquired, and consist in elongation of certain segments of the intestine, abnormal length of mesentery, and adhesions. 2. Irregular distribution of intestinal contents and violent peristalsis are the most important exciting causes. 3. Volvulus is most frequently met at the sigmoid flexure and the lower portion of the ileum. 4. Secondary

Digitized by Google

volvulus on the proximal side of other forms of intestinal obstruction is not a rare occurrence; it is also frequently developed during an attack of peritonitis. 5. As a rule, the symptoms are more acute and intense if the volvulus is located above the ileo-cæcal region. 6. Vomiting in cases of volvulus of the sigmoid flexure is not a constant symptom. 7. The most important physical sign of volvulus is a circumscribed area of tympanites which corresponds to the location of the volvulus, but this sign is only of value before general tympanites has set in, and therefore enables the surgeon in many cases to make an early and positive diagnosis. 8. All cases of volvulus should be treated by laparotomy if reposition cannot be accomplished by rectal insufflation of hydrogen gas. 9. Reposition should not be attempted without evisceration. 10. Evacuation of intestinal contents by a free incision should be practised in every case where general distension of the intestines is present. 11. Enterectomy becomes necessary if any considerable portion of the intestinal wall has become gangrenous. 12. Irreducible volvulus should be treated by establishing intestinal anastomosis with permanent exclusion of the seat of obstruction from the active fæcal circulation. 13. Recurrence of volvulus can and should be guarded against by shortening the mesentery by folding it upon itself parallel to the long axis of the bowel and suturing the apex of the fold to the root of the mesentery."

A "STRIKE" AMONG MEDICAL MEN.

MEDICAL MEN are generally so "easy to be entreated," and so ready to yield to any call of urgency, that the public has come to think itself entitled to their services as if they were under some compulsion to be at everybody's beck and call. But in these days of strikes this notion may have to be reconsidered. At Rodez, in France, the medical men, backed by the Medical Association, refused to make a post-mortem examination of the body of a young woman found in a field, on the ground that the fee allowed was too small. For more than a week the body remained unexamined, and some suspected prisoners had to be released in the absence of confirmatory medical evidence. Some of the doctors have been fined for their behaviour, but are appealing to the Cour de Cassation. The question has been discussed in the French Senate, who find they have no more power over doctors than over pitmen, if they use no violence and break no law. No body of men have such good reason for combining as medical men, and none could inflict more effective vengeance on those who underrate their services. But it ought to be possible to bring the public to a better appreciation of our deserts without the arbitrament of a "strike."

MICRO-ORGANISMS IN WATER.

THERE is a difference of opinion amongst many chemists as to whether the presence of a large quantity of bacteria or a considerable amount of organic matter in drinking water justifies as such its condemnation. Waters containing few bacteria and little organic matter have been known to produce distinctly injurious results, while some waters containing much of both appear to be comparatively harmless in their action. Of course, very much depends upon the source of the water and the nature of its surroundings. The fact, however, that organisms believed to be agents in bringing about certain diseases exist in water for a long time, during which their activity is preserved, makes their absence distinctly desirable. Certain operations in nature would seem to indicate this. Investigations have shown that more bacteria are usually present in rivers than in lakes, in spite of the fact that lakes themselves in many cases are more or less polluted by rivers passing through populous towns. In a very interesting paper in the *Zeitschrift für Hygiene*, 1889, 86, B. Krüger considers that this rapid decrease in the number of organisms may very possibly be due in part to the action of direct sunlight, but in the main to the tendency of water in a comparatively undisturbed state to deposit and precipitate. He therefore carried out a number of experiments with a view to determine how far the removal of organisms was brought about by the mere mechanical deposition of inert matter and also by precipitation as a result of chemical action. The mechanical precipitants employed, all in a state of fine powder and sterilised, were alumina, brickdust, clay, chalk, sand, coke, and charcoal. Water obtained from an ordinary service pipe was impregnated with a liquid containing bacillus growth of a species incident to tap water. This was divided into two portions—one for precipitation with the inert substance and the other untreated for the sake of comparison. Experiments were similarly carried out in which precipitation was obtained as the result of chemical action such as is brought about by the addition to the water containing naturally lime, magnesia, &c., substances like wood ash, sulphate of alumina, and slaked lime. The general conclusion come to by the author from the results obtained is that undoubtedly large numbers of bacteria are carried down by inert substances merely sinking in water, but that the action is very considerably increased when, in addition to mechanical deposition, a chemical precipitation also takes place. The corollary is evident—inert substances do mechanically assist in the precipitation of micro-organisms, but preference should be given to chemical treatment.

SECRET JUDICIAL INQUIRIES IN RELATION TO PUBLIC MORALS.

IN a libel action which was recently brought to trial, Mr. Justice Denman, having before him the pleadings in the case and gathering therefrom that the evidence which would be tendered was such as it was not desirable in the public interest to receive in open court, decided to exclude the general public during the hearing. It happened that among the number so excluded was a member of the bar, who has challenged the right of the Judge to take the step, and has submitted the question for the opinion of the Attorney-General. The opinion expressed by that authority is that the Judge exceeded his powers, and that there is no precedent for the exclusion of the public at the hearing of libel actions. This of course is only a dictum, but it suffices to detract from the authority of the precedent which Mr. Justice Denman created when he assumed the other day to clear his court upon the grounds already indicated. It may well be therefore that in future judges will hesitate to follow that example, and it should perhaps be considered whether it is not for the public advantage that a judge of the Supreme Court should be invested with the power, conferred if necessary by legislation to that effect, to hear in private any cause which seems to him calculated to bring forward evidence not fit for publication. The question is undoubtedly a very involved and difficult one. The publicity of judicial proceedings has very rightly been regarded time out of mind as one of the best safeguards which the constitution provides against the perpetration of injustice by judicial means. The free right of access to the courts is therefore a right which should be jealously guarded. But this right is not seriously imperilled by excluding a certain class of cases from its operation. Indeed, that is done already, and the only question now open to discussion is the question whether the existing custom should be extended at all. In cases where it appears that the evidence will bring out the details of practices which are better not described,

Digitized by Google

and where it must be fraught with evil suggestions, we think some discretion might usefully be confided to the presiding judge, especially when the issues before the tribunal are not those of a criminal proceeding where a prisoner's liberty is at stake, but only those of a civil trial where the question to be determined is simply the liability of one party to perform a duty or forfeit a penalty for the benefit of the other.

PSOROSPERMIA (COCCIDIA) IN MAN.

As will be seen from the report on another page, a large part of the time of the last meeting of the Pathological Society was occupied by the description of certain parasites which, although remarkably prevalent in some of the lower animals, notably the rabbit, have not been much recognised in the human subject. Indeed, the specimen shown by Mr. Bland Sutton suggested the notion that possibly its presence has been overlooked in many cases. For his specimen was obtained from the Middlesex Hospital Museum, where it had been mounted as an example of mucous cysts of the ureter. Mr. Sutton, however, correctly surmised the parasitic nature of this curious specimen, for on recently submitting the "cysts" to microscopical examination, he found that they were really occasioned by the presence of psorospermia or coccidia, of which Leuckart has written so able an account. Of equal interest were the communications by Mr. Silcock and Dr. Delépine, the former dealing with a case in the human subject, where these parasites were found in the liver and spleen, and to the presence of which it was supposed that the obscure febrile symptoms were due; whilst the latter gave a most careful account of the disease in the rabbit. Dr. Payne's remarks deserve consideration, for, referring especially to the peculiar bodies characteristic of molluscum contagiosum, and lately alleged to be psorospermial in nature, he pointed out the difficulty of distinguishing them from colloidal masses derived from cell degeneration. Moreover, Mr. Sutton admitted that it was possible to mistake the ova of some entozoal worms for psorospermia. Nevertheless the attention thus given to the subject is sure to bear fruit, and without admitting it to be conclusively proved that these minute animal parasites are responsible for eczema of the nipple or molluscum contagiosum, the question of their gaining entrance into the human body, and being there a source of danger to health and even of life, is too important to be lost sight of. The "gregarinidæ' are perhaps the most widely diffused of all animal parasites, since they infest insects and other invertebrates, and their occurrence in man has hardly hitherto been seriously regarded. But they at once assume a most important position if they are to become responsible for tissue changes of a grave kind. The subject, however, from this point of view, is still in its infancy, and no good result will accrue from premature generalisation on the few data at present forthcoming.

PAUPER INEBRIATES AND THEIR COMPULSORY TREATMENT.

DR. W. M. DUNLOP, medical officer of the St. Pancras Workhouse, in a letter addressed to the Workhouse Visiting Committee, has expressed himself strongly in favour of the suggestion of Dr. Norman Kerr—that the guardians of the poor should be invested with a discretionary power of paying for the detention of pauper inebriates, either in the workhouse or in some special institution for the treatment of inebriety. He divides inebriate inmates into two classes:—1. Those placed in the insane wards suffering from acute alcoholism, and those suffering from dementia from chronic alcoholism; these cases comprise over 25 per cent. of the total admissions into the insane ward. They are at present dismissed as soon as the symptoms disappear. 2. The ordinary inmate of the workhouse, who takes his discharge habitually or occasionally, and who as frequently returns intoxicated. Such powers of detention could only be conferred by special legislation. Dr. Dunlop does not make clear whether the pauper is in the first instance to be a consenting party to this detention, as in the case of other habitual drunkards, or whether he has to be favoured by deprivation of liberty without being consulted. His frequent dependence on the rates, and the fact that otherwise he is likely to be a constant charge, make the gift of these compulsory powers not unreasonable from the ratepayer's point of view. From the pauper's point of view they are his only chance. It lets in light, both on pauperism and insanity, to learn from Dr. Dunlop that 25 per cent. of the insane cases in workhouses are of alcoholic causation.

CLINICAL TEACHING ON FEVERS IN GLASGOW.

IT will be lamentable if the establishment of St. Mungo's School in any degree curtails the range of clinical teaching, especially in the matter of fevers. The letters in the daily papers on questions in dispute between rival schools are not seemly or satisfactory. We had much pleasure some time since in noticing Dr. Allan's efforts to give clinical instruction in fevers, and in holding his example up for imitation by other schools and teachers. We have recognised the attempt to utilise to the full the splendid clinical field of the Royal Infirmary. So that we claim to be in full sympathy with all teachers in Glasgow, whether extra- or intra-mural, who wish to make medical education real. Dr. Gairdner, in a letter to the *Glasgow Herald*, takes, and apparently quite justly, credit for having been among the first to induce Dr. Allan to commence his teachings in fever, which have been so successful, and he is concerned to think that between the fires of the two schools Dr. Allan threatens to withdraw from both. Dr. Gairdner disclaims all university jealousy, and seems only anxious that, in any new teaching arrangements into which Dr. Allan may enter, he may not compromise the interests of the university students. Surely the Fever Hospital of Glasgow and its lessons should be neutral ground on which both university and extra-mural schools might agree to meet. We congratulate Dr. Allan on being so appreciated by both sides, and urge upon him to continue the teaching which has been so successful. We doubt if in any other school in the country a clinical teacher of fevers could boast of forty pupils.

CABS AND INFECTION.

IN the absence of anything like a public service of ambulance carriages it frequently happens that a cab is found to be the most convenient means of conveying patients suffering from infectious disease from their homes to the nearest fever hospital. The disinfection of these vehicles is of course a matter of much importance, and the question how and where this may best be carried out has lately given rise to some discussion. A contemporary suggests that in the case of hospitals under the control of the Metropolitan Asylums Board this body should be responsible for the disinfection and not the Local Board of Works, whose offices may be placed at some distance. In point of convenience there is doubtless an appreciable difference between the two methods of procedure. The danger of allowing a cab to traverse the public streets after depositing its infectious occupant is a further consideration. While we cannot regard this risk as of great practical importance in itself, inasmuch as it is much qualified by that best of purifiers, fresh air, there are conceivable circumstances in which it might excuse a natural feeling of alarm. Such,

Digitized by Google

for example, are afforded by the delay consequent on blockage of traffic, by the importunity of foot-weary or hurried wayfarers, or the regardless cupidity of the driver should a tempting fare prove too much for his scruples as to infection. It is probable, however, that in the great majority of cases such causes of alarm have little foundation, and the proposed interchange of authority would, after all, exert no very extensive alteration in present usage. In these circumstances we are disposed to wait for proof of the mischievous consequences attributed to the present system before advocating a change, which might not, after all, be wholly free from objection. Of much more serious import is it that disinfection, by whatever authority it is carried out, should be of the most thorough character.

VENESECTION IN CHLOROSIS.

THE practice of venesection in chlorosis would not at first sight appear likely to yield good results, but that it is capable of acting most beneficially is vouched for by Dr. Wilhelmi, who has for some time past employed it with great success in typical cases of chlorosis (not of lead poisoning, as was by an error printed in last week's issue). About three or four ounces of blood only should be taken, the patient being in bed and being covered up with blankets and plied with hot drinks until sweating comes on. It would appear that the severer the case the more benefit may be expected from the bleeding, but that this treatment is of little use in mere hysterical or symptomatic anæmia.

THE SELBY OAK CASE.

WE need not comment at any length on this case—unfortunately another illustration of the fact that a medical man is daily at the mercy of unprincipled or insane women. We congratulate Mr. Cuthbert on his complete vindication. The case is also another illustration of the use of the Medical Defence Union. Nevertheless, the frequency of these cases only serves to show the necessity for medical men multiplying the securities by which their conduct when exposed may be vindicated.

CAROTID ANEURYSM.

THE operation of ligature of the common carotid below the omo-hyoid for aneurysm of that vessel was performed by Mr. James Hardie, of Manchester, on the 4th inst., in the case of a gentleman aged forty-five. Up to the present time he has progressed favourably in every respect. We hope to give a full report of the case in due course.

BETHNAL-GREEN POOR'S LAND FOR SALE.

THE question respecting the disposal of Bethnal-green Poor's Land, as our readers may have learned elsewhere, is, after all, one of money. At present the land is let to the Bethnal House Asylum, and yields an annual income of £120. If it were thrown open to the public this rental would of course be lost. If, as was lately proposed, half the ground were utilised for building various municipal offices, a considerable sum by way of compensation would be paid out of the local rates to the Charity Commissioners on behalf of the poor. Naturally the Commissioners, supported as they are by a bare majority of the trustees, feel disposed to close with an offer so advantageous, notwithstanding that it is directly opposed to the terms of the bequest under which the land is now held. The readiest way out of the difficulty is by having recourse to public subscription. It has therefore been proposed to raise in this way £5000, no great price for six acres and a half of ground, but a sum which will at the same time satisfy the claims of the local poor, and will save another open space—not one too many—in one of the most populous metropolitan districts. With this object an appeal, strongly supported by local and external influence, has just been issued, and payments will be gladly received by Messrs. Barclay, Bevan, Ransom, and Co. In adding our testimony to the importance of this movement, we feel that we are simply discharging a double duty to the destitute poor and the overcrowded population of East London.

MEDICAL ITEMS FROM FIJI.

MR. B. G. CORNEY, chief medical officer of Fiji, has been appointed an official member of the Legislative Council of the colony. The health of the Europeans has been excellent. In Suva, with a population of about 700 Europeans, there have been but six deaths. Of these three were of infants, one was a sailor and non-resident, and of the two deaths which were of *bonâ-fide* adult residents one was from old age. A cottage hospital has been opened in Levaka (Fiji), and is being supported by private subscriptions, the only contributions from public funds being in the shape of the gratuitous services of the district medical officer.

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—Dr. Bramann has been promoted to the rank of Extraordinary Professor of Surgery.

Bologna.—Dr. Pellacani, Extraordinary Professor of Pharmacology in Genoa, has been appointed, after open competition, Professor of Forensic Medicine.

Cadiz.—Señor Löhr has been selected, after competition, for the chair of Hygiene, and Señor Guedea y Calvo for that of Clinical Surgery.

Palermo.—Dr. Marcacci has been appointed Professor Extraordinary of Physiology.

Prague (Bohemian University).—Dr. C. Schwing has been promoted to the rank of Extraordinary Professor of Midwifery and Gynæcology.

St. Petersburg.—Dr. Hoyer, Professor of Embryology and Histology, has been reappointed for a further term of five years, although he has completed thirty years of service. Ninety-five students have passed their final examination this term; of these, thirty-five obtained the note "very good" in more than one-half of the subjects, thus gaining the right to remain at the Academy for further study.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following eminent foreign medical men are announced:—Dr. Grigoroff, Ordinator of one of the Moscow Hospitals, and author of works on Syphilis; Dr. R. Hüber, of the Maria Magdalen Hospital, St. Petersburg; Dr. Ernst von Kade, who acted as assistant to Pirogoff during the Crimean War.

DR. GAIRDNER of Glasgow has lately delivered an address to the Midland Medical Society, in Birmingham, on Drunkenness and Dipsomania: Medical and Legal Preventives and Remedies. He strongly supported more stringent measures for the compulsory detention of habitual drunkards, and on the same lines as those for the treatment of the insane. No medical practitioner of experience can fail to see the absurdity of making the detention of habitual drunkards turn on their own consent.

MR. T. H. OPENSHAW has been elected Surgical Registrar at the London Hospital, in the place of Mr. J. Hutchinson, jun.

PROFESSOR LEYDEN has been summoned from Berlin to a consultation with the Czar's physicians.

Digitized by Google

WE learn that Mr. William Anderson, whose nomination as one of the three candidates for selection for the Challis Chair of Anatomy in the University of Sydney we reported in a previous issue, has withdrawn his application for the post.

THE Council of King's College has appointed John Phillips, M.A., M.D., Assistant Physician Accoucheur and Assistant Physician for Diseases of Women and Children, F. F. Burghard, M.D., M.S., Assistant Surgeon, and G. L. Cheatle, M.R.C.S., Sambrooke Surgical Registrar.

THE proposal of the Brighton Sanitary Committee for the Council to hold a meeting early in the ensuing year to adopt the Notification of Infectious Diseases Act at that town has been overwhelmingly rejected by the Council.

IMPROVED FACILITIES FOR INVALID TRAVELLING BY RAIL AND SEA.

CALAIS AND THE NEW HARBOUR.

(FROM OUR SPECIAL CORRESPONDENT.)

The Old Town and the New.—The Increase of Population.—The Registration of Foreigners.—Travellers and Port Improvements.—The Water-supply and Drainage of Calais.

THE old town and fortress of Calais, which for so long were associated with the varied fortunes of English history and English arms, and which, in the main, were built by Englishmen, are now but a memory of the past. The grey and stout city wall the English built has been destroyed, the protecting moat is filled over, and contains now a modern egg-shaped sewer of recent construction. Here and there an old gateway with its drawbridge remains, and is preserved as a historical monument. Then the fine old belfry, with its harmonious silver-toned chimes, which the English also built, still stands erect and majestic, and is likely to be for many a long year the chief architectural attraction Calais can offer to its foreign visitors. All these things are but vestiges of the past. Calais, even as a municipal entirety, has also ceased to exist. The old and quaint Town Hall is empty, the Council Chamber is silent. The antique and historical town of Calais is now merged into, and almost swallowed up by, the very modern, but more prosperous and larger, suburban and manufacturing commune of St. Pierre. At the Town Hall of St. Pierre the Municipal Councillors of Calais now sit and deliberate, and all public questions either relating to health matters or other interests must be treated in common. Yet, so recently as 1885, these two communities were absolutely separate. Now they are both firmly bound together by the iron link of a most extensive circle of fortifications. Those whose experience of military matters does not extend beyond our pacific island home, can have no conception of the magnitude of the Calais fortifications; and when we complain of the neglect of sanitary works in France, and vaunt their greater development in England, we should bear in mind that, as we have not been compelled to squander public wealth on such extensive military defences, we are better able to afford the cost of sanitary improvements. The new fortifications of Calais now embrace both St. Pierre and Calais, and thus no scheme of drainage, water-supply, hospital accommodation, &c., can be entertained which does not deal with the two communities. As the population of Calais is estimated at 14,000 and that of St. Pierre at 44,000, it will be seen at once how completely the position of affairs has been altered. At Calais the houses are very old, and often closely cramped together. At St. Pierre the houses are all quite new. The population of Calais has increased, but in a very slow ratio when compared with that of St. Pierre. Thus in 1827 there were 9459 inhabitants at Calais and 4957 at St. Pierre—total, 14,416. In 1857 St. Pierre was ahead, the figures being: Calais, 11,979; St. Pierre, 12,422—total, 24,391. Ten years later, in 1867, while the population of Calais remained almost stationary—i.e., 12,723—St. Pierre rose to 17,294—total, 30,021. Now, as already remarked, out of a total of 58,000, 44,000 belong to St. Pierre.

All these facts must be taken into consideration in order to understand how great the transition has been; and, without such general knowledge of the situation, it would be impossible to deal with sanitary problems involved. These, it must be confessed, have been strangely neglected; but I would not wish to complain of the neglect in this respect without acknowledging how great is the progress effected in other matters. To the traveller from England the enlargement of the port is the first thing noticed. By the constant use of dredgers and two powerful sluicing basins the depth of the channel will be maintained with 13 ft. of water at the lowest spring tides, giving at the pier-head at high water from 29 ft. 6 in. to 37 ft. 9 in. of water. The largest sluicing basin is not, however, yet completed. Nevertheless, the service of the Channel packets between France and England can be carried out at the North Quay at all hours and under all conditions of tide. I saw one of the largest steamers swing round within the port just an hour before low tide. This saves the passengers a very unpleasant experience. Formerly such a ship would have had to back out of the harbour and turn round when once at sea. Most extensive tidal docks have been constructed, some with 26 ft. 3 in. of water, others with 23 ft. 6 in. of water. These docks are connected with eight lines of railway. Steam and hydraulic cranes exist for the use of the ships, and there are admirably built store-houses for merchandise. The canal communication with the port has also been improved, so that now the largest barges can come to Calais. No one can contemplate these vast ameliorations without being impressed by the gigantic character of the works and the immense change which has been effected. Needless to say that this opens out a new and a most urgent sanitary problem. It has already been seen how rapidly the joint populations of St. Pierre and Calais have increased of late years and before the new port was built. What, however, will be the increase now that great works are terminated, and what interest have we in England in such development? Our interest is clearly defined, and it is twofold. First, there is no other foreign port through which so many Englishmen pass in the course of the year. Secondly, there has been a great augmentation in the resident English population of Calais and St. Pierre.

When inquiring into the sweating system in various English towns I was constantly met with the suggestion that a pole tax should be inflicted on foreign workmen, or that the importation into England of foreign pauper labour should be prohibited. Without seeking to discuss in detail, in this place, the economic problem involved in such proposals, it struck me as a somewhat narrow view to take, as it seemed like the policy of the politicians who, on this subject, did not see beyond their back yards. Public health undoubtedly is compromised by the dirty habits of some of the foreigners who settle in our great towns. Their presence does occasion overcrowding, and contributes to so lower the rate of wages in certain and special trades that the workers cannot earn enough to keep themselves in health and strength. But how much greater would be the overcrowding and fatal the fall in wages if all the English workers who now earn their living abroad were sent back to England, or even if foreign countries refused to admit any more strangers. The main industry at St. Pierre-les-Calais is the manufacture of tulle, and this delicate material is made to some extent with English machinery and to a large extent with the aid of English workmen. The French Government, also troubled by the presence of so many foreigners in France—their number in proportion is far greater than the number of foreigners who live in England,—recently issued a decree to the effect that all foreigners resident in the country must register their names. No less than 1700 foreigners have thus been registered in Calais. As it is only the head of the family who makes the declaration this represents probably a population of some 5000 people. It may be said therefore that from 8 to 10 per cent. of the resident population of Calais are foreigners registered as such. The details concerning the 1700 persons now registered have not yet been fully drawn up; but I have an analysis of the 1512 declarations first made. Naturally, being the closest neighbours and natives of a country where wages are not so high as in

Digitized by Google

France, the Belgians stand first on the list. Out of the 1512 foreigners registered 651 are Belgians, and this number represents 531 men, 401 women, and 768 children; a total therefore of 1700 Belgians. Next on the list are the English, who have made 552 declarations, which represent 379 men, 374 women, and 726 children; total 1479 British subjects. The remaining 309 declarations comprise a variety of other nationalities. As the total of the 1203 Belgian and English registered families represents a population of 3179 men, women, and children, it is probable that the 1700 foreigners now registered constitute with their families, as I said before, a total population of 5000 persons. The great majority of the English come from Nottingham, and I am not aware that the rate of wages at Nottingham is so very high as to support easily the return of these workers to their native town. Yet, if we drive foreigners away from England, it is only natural to expect that Englishmen will be sent back to us from abroad; and the method of registration adopted—the figures I have just given—show that the French have already taken measures to do so at any moment if they think fit.

Naturally, with the development of the Port of Calais, the number of English and foreign residents is likely to still further increase; while the augmentation of the passenger traffic is quite fabulous, and altogether out of proportion to the other French ports. The following table, giving the yearly number of passengers between England and France by the three principal routes, sets forth this fact in a conclusive manner:—

	Calais.	Boulogne.	Dieppe.
1880	197,916	147,606	69,565
1881	204,591	157,034	78,831
1882	223,391	144,310	81,090
1883	210,199	126,635	85,084
1884	183,433	97,050	67,156
1885	190,595	96,077	62,604
1886	215,984	118,877	67,419
1887	235,695	113,007	65,835
1888	247,870	106,678	68,970
1889	332,230	106,427	179,099

The figures for 1889 are only given for the eleven months and conclude on Nov. 30th.

These figures set forth in eloquent terms the extraordinary success achieved by the Calais route in comparison with its rivals. They also show that the sanitary condition of Calais is a matter of international importance. Yet sanitary matters have, unfortunately, been neglected, and this is probably the reason why the death-rate is high. Many other French towns, however, are not better off in this respect than Calais. During the last five years the death-rate seems to have varied from 24 to 27 per 1000 per annum. It would, doubtless, have been higher still but for the fact that Calais at least possesses a good water-supply. This is derived, at a distance of about eight miles, from Guines, the place celebrated in history as the Field of the Cloth of Gold. Here the soil consists of sand and small stones with an under-stratum of clay and sandy soil. The water comes from below the clay. It is gathered by a system of subsoil drainage, and is pumped up into reservoirs at a height of fifty-five metres, assuring to the town of Calais a pressure of forty metres. The water, after filtration, is delivered in iron pipes, and is thus protected from accidental contamination. The supply should amount to seventy-five litres per head per day; but the tulle factories take more than their share and thus reduce the general supply. The water is pure, though it has the very general defect of being too calcareous. Also there is the more important objection that the supply is not compulsory and private wells are still tolerated. In the better class of houses, of course, they have been abolished, and the town engineer assured me that nothing but the town water-supply was drunk at the hotels and cafés. Still, wherever the use of private wells is allowed there is always some danger. In a town like Calais wells are all the more dangerous as the cesspool system is still enforced. Indeed, the idea of abolishing cesspools has not yet dawned on the authorities. They acknowledge that the construction of sewers would be a good thing, but this only on the old French model—that is, sewers destined to receive the rain and slop water, and not the soil. Perhaps, however, when the progress accomplished in Paris in this respect is better known, the authorities may change their opinion. In any case, the drainage of Calais, and especially of St. Pierre, is especially difficult, for the simple reason that there is no fall. A great number of places are actually below the level of the sea; and if it were necessary, for the sake of resisting an invading army, the whole of the surrounding district could be flooded. Most of the streets have no sewers; there is surface drainage for slop water, and the rest goes into the cesspools. There are, however, two large sewers and some minor sewers. Several of these have their outfall in the inner basin of the old port, which faces the old and abandoned railway station of Calais town. Many travellers will remember the abominable odours that prevailed at this spot when the tide was out and the fishing-smacks lay softly in the mud. This little basin is called the Basin du Paradis, a name which might have been given satirically. Strange to say, those who make the greatest use of the basin object to its being cleansed. The town has several times tried to dredge it out, but the shipowners staunchly objected, on the ground that their ships would be injured if they did not have plenty of soft mud to rest upon when the tide went out. The town engineer (M. A. Dagniault) has drawn up an entire plan for the draining of the whole town, and, in spite of the unfavourable topography, contrives to give a fall of 2 in 1000 to his sewers. But there seems no prospect of this scheme being adopted at present, as public opinion is not yet alive to the importance of the subject. A new sewer has, however, been constructed of late. It runs along the Rue Bertoire, and thence pursues the course of the moat that was in front of the old rampart, falling into the Basin du Paradis. It is an egg-shaped sewer, eighty centimetres broad, and receives about two-thirds of the drainage of the old town, or of Calais proper.

All these facts show how much behind the town of Calais is in matters of sanitation; but the worst still remains to be related. There is a small district at the foot of the lighthouse of closely built fishermen's dwellings, where the houses are utterly devoid of any sort of sanitary accommodation. Not only are there no closets, but the inhabitants strongly object to the presence of them. Also, the houses have often several owners, and if one consents to the construction of a closet, the other and joint owner will probably object. The authorities have sought to solve the difficulty by building a shaft, which is placed unpleasantly near the fish market. Here, every morning, the inhabitants of this little district come and empty their vases containing the night soil. Of course this is not thrown down the shaft with very great accuracy of aim, so that those who arrive late cannot approach the opening, and content themselves with throwing their filth on the sides and the ground. Thus every day, and till the scavengers come to clear up and flush the place, a fearful nuisance is created. The district which rejoices in this primitive method of draining is called the Courgain, and, at a distance, seems one of the most picturesque parts of Calais. The time has surely arrived when public attention should be called to such a state of things. The existence of these grievances is not known and not realised by the public at large; but now that Calais is flooded by passengers from all parts of the world, it is urgent that these defects should be brought to the notice of the public and the authorities. Fortunately the houses are low in Calais, and the town, quite unsheltered, is exposed to the four winds. This doubtless contributes powerfully to purify the atmosphere.

Calais, December, 1889.

MEDICAL TRIAL.

LEESON *v.* THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION AND MARSHALL.

THIS was a motion brought in the High Court of Justice, Chancery Division, before Mr. Justice North, on Friday, the 13th inst., on the part of Mr. Joseph Frederick Leeson, a physician, to restrain the General Council of Medical Education and Registration from removing his name from their Register of general practitioners until the trial of the action, and from publishing resolutions passed by them on Nov. 28th, 1889, to the effect that he, Mr. Leeson, had been guilty of infamous conduct in a professional respect, or their direction to their registrar to erase his name.

Digitized by Google

Mr. Cozens-Hardy, Q.C., and Mr. George Henderson, for the plaintiff, in support of the motion, said they could not, on the authorities, ask his lordship to go behind the finding of the Council if it was a matter within their jurisdiction regularly and *bonâ-fide* conducted. They contended, however, that the inquiry was bad for several reasons—that their own rules had not been complied with; that the inquiry was (as they said) as to whether Mr. Leeson had covered Mr. Harness in acting as medical electrician, a matter he had a right to do; that it was directed against Harness while professedly made into the conduct of Leeson; and that two of the judges were incapacitated so as to vitiate the whole inquiry, because they were members of the Medical Defence Union.

Mr. Everitt, Q.C., and Mr. Muir Mackenzie, for the Council, contended that the proceedings had been honestly and regularly conducted, and the court could not go behind the finding of the Council.

Mr. Justice North, on the question of the construction of the letter formulating the charge against Mr. Leeson, which he observed had not been very happily expressed, came to the conclusion that the plain meaning of the charge was that Mr. Leeson had been acting as cover for Mr. Harness, not merely as a medical electrician, but as a person acting as a registered practitioner; and so it had been understood and acted upon by all persons who had anything to do with the inquiry. Had it been otherwise it would have been in his power, and would have been his duty, to interfere. It being, however, an inquiry as to whether Mr. Leeson had acted as cover for an unqualified person to act as a registered practitioner, it was a matter in which, in his lordship's opinion, the Medical Council were alone the judges, and which he ought not and could not judge of subject to their acting regularly and *bonâ fide*. Upon this part of the case it was said that a standing order or rule had been made on the very day of the inquiry for the mode of conducting such inquiries, and at first sight that did look strange; but, on looking at what was actually done, he was convinced that the rules were only what ought to have been made, and the inquiry would have been conducted in the same way if the rules had not been made. Another matter of complaint dealt with by his lordship was that the mode of conducting the inquiry laid down by the Council's standing orders had been departed from by allowing the solicitor of the Medical Defence Union to take it up at a certain point. That, his lordship thought, was within their power, and was not prejudicial or unfair to the person accused. Another point taken on the part of the applicant was that certain matters had been before the Council in the inquiry that were not evidence. The Council, he pointed out, were not in a position to administer oaths, and could not be guided only by what would be strict evidence in a court of law. He did not consider that the proceedings were in any way invalidated by such a cause as that. There was another point on which he had some hesitation, it being a point of law, as to whether, the parties having a right to have it decided at the hearing, he ought not to postpone it, and there was a question for the trial whether the injunction ought not to go; but being satisfied, as he felt, that on other grounds there was no case for an injunction, he took upon himself the decision of what was a point of law at this stage. The point was whether the judicial proceedings of the Council were invalidated by reason of two members out of some thirty who sat on the investigation being interested parties. If they were interested, it was clear law that the proceedings would be invalidated; but was it necessary that their interest should be a pecuniary interest for that result to follow? In this case the two members of the Council were subscribers to the Medical Defence Union of 10*s.* a year, and were under a guarantee to that society, the society being, in fact, the prosecutors. To consider the effect of this argument his lordship looked at the objects of the Union, which comprised not only the prosecution of unregistered practitioners and the removal of persons guilty of unprofessional conduct, but the protection of practitioners. They were perfectly impartial; their duty as members of the Union was as much for the protection of Mr. Leeson as a qualified practitioner as to have him removed if he ought to be removed. This point of law, therefore, his lordship decided in favour of the defendants There was one other point his lordship dealt with. It was argued that the inquiry was not *bonâ fide* because the acts and conduct of Harness had been gone into, and it was said the inquiry was not really into Leeson's conduct so much as into Harness's. That was so in a sense; but it was necessary and proper to inquire into Harness's acts for the purpose of seeing what it was that the accused was acting as a cover of; and that being so, he could not say the inquiry was not *bonâ fide*. His lordship therefore refused the motion.

This decision of Mr. Justice North was appealed against by the plaintiff on Wednesday the 18th inst., in the Court of Appeal, before Lords Justices Cotton, Bowen, and Fry.

Mr. Rigby, Q.C., Mr. Cozens-Hardy, Q.C., and Mr. George Henderson appeared for the appellant; Mr. Everitt, Q.C., and Mr. Muir Mackenzie for the General Medical Council; and Mr. Sebastian watched the case for the company, who were not parties to the action.

The arguments were concluded on the following day, when their lordships announced that it was their intention to reserve judgment, and expressed a hope that they might be able to deliver it on Saturday, the 21st inst.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Typhoid Fever at Longton, by Mr. SPEAR.[1]—Longton is one of the southernmost of the pottery towns in Staffordshire, and after certain regular occurrences of fever amongst its 35,000 inhabitants for a number of years past, 16 deaths from typhoid fever occurred in 1888, and 13 more in the five months January–May of the present year. In all, during this latter period of seventeen months Mr. Spear heard of 66 household invasions, representing 155 attacks, and as he was able to regard these as the total occurrences of the disease that had taken place he sets the mortality rate at nearly 19 per cent., which must be regarded as an unusually high one. Considerable details are given in the report as to the incidence of the disease, in the respective months, on age, and on sex; and it is pointed out that in no less than 35 houses multiple attacks took place; these, in some instances, amounting to seven and eight in a single house. Only 14 second attacks took place within a fortnight of the first one, and having regard to dates and to the circumstances of household attacks which are set forth in some detail, Mr. Spear feels justified in regarding defective local sanitation, and especially the faulty methods for the disposal of excremental refuse about dwellings, as having afforded the necessary means by which the poison of typhoid fever, when once introduced, had opportunity for spreading itself. But there still remain a number of primary invasions in families to account for, and all the various causes usually associated with typhoid fever are considered in this connexion, the result being that milk and food supplies, sewerage and drainage are set aside. The question of water-supply is dealt with at considerable length. The service is in the hands of the North Staffordshire Water Company, and details are given as to all the various sources from which the supply is derived, and as to the methods in which mingling of waters derived from different sources takes place before the supply reaches the different towns and places within the area of the company's service. Some suspicion did seem to attach to one of the sources in question, and this was, to some extent, endorsed by the result of chemical analysis. The question of possible pollution during transit from the company's works along mains and pipes to the several households and localities is also entered into; but the whole service was found to be very complicated, and in the end Mr. Spear was unable to go beyond expressing a fear that, as regards the medium by which the several scattered initial cases which appeared as independent foci had arisen, the water-supply was not free from suspicion; and he states that one supply especially—namely, the Normacot service—appeared to demand close attention. This view is maintained in certain recommendations appended to the report; and especial reference is there also made to the need for effecting improvement in the closet accommodation of the district by

Eyre and Spottiswoode, East Harding-street, E.C.; Adam & Charles Black, Edinburgh; Hodges, Figgis, & Co, Dublin. Price 6*d.*

Digitized by Google

means either of waterclosets or of privies of such capacity that storage of excremental refuse in the vicinity of houses shall be limited to accumulations of not more than one week's duration.

Diphtheria and Enteric Fever in the Penistone District, by Mr. SPEAR.[1]—The diphtheria in this district followed on a somewhat similar prevalence during 1881–82, and sporadic cases of diphtheritic sore-throat have since been by no means uncommon. This is an important fact as bearing on the subsequent prevalence in 1888–89, when fifty-seven households and 103 persons were attacked in Penistone and Thurlestone, and the mere circumstance that the connecting link between the occurrences could not be actually traced in no way detracts from the significance in sequence of the several events. There have also been two occurrences of enteric fever—one in the Penistone rural and the other in the Thurlestone urban district. The former had a Board school for its centre, and there appears but little doubt that water-pollution was associated with it; and this notwithstanding the fact that the results of chemical analysis could not satisfactorily decide as to this. The occurrence at Thurlestone could not easily be traced to its source, but the conditions of excremental pollution which were found to be associated with it were precisely those so commonly identified with the appearance and spread of this disease. Unfortunately, as regards the Penistone urban district, advice given in 1887 by Dr. Gresswell has hardly been acted on. Much sanitary amendment is also called for in the Penistone rural sanitary area.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5646 births and 4235 deaths were registered during the week ending Dec. 14th. The annual rate of mortality in these towns, which had been 18·2, 19·0, and 21·5 per 1000 in the preceding three weeks, further rose last week to 23·1. During the first eleven weeks of the current quarter the death-rate in these towns averaged 18·8 per 1000, and was 2·1 below the mean rate in the corresponding periods of the ten years 1879–88. The lowest rates in these towns last week were 17·1 in Norwich, 18·0 in Brighton, 18·0 in Derby, and 19·2 in Birmingham. The rates in the other towns ranged upwards to 31·1 in Manchester, 31·9 in Oldham, 32·3 in Blackburn, and 34·7 in Plymouth. The deaths referred to the principal zymotic diseases, which had been 343 and 383 in the preceding two weeks, were last week 378; they included 105 from whooping-cough, 74 from measles, 63 from scarlet fever, 59 from diphtheria, 40 from "fever" (principally enteric), 37 from diarrhœa, and not one from small-pox. These zymotic diseases caused the lowest death-rates during the week in Leicester and Huddersfield, and the highest rates in Bolton and Plymouth. The greatest mortality from whooping-cough occurred in Portsmouth, Bolton, Hull, Wolverhampton, and Bristol; measles in Derby, Nottingham, Bradford, and Sunderland; scarlet fever in Liverpool, Wolverhampton, Bolton, and Plymouth; and "fever" in Birkenhead. The 59 deaths from diphtheria in the twenty-eight towns included 35 in London, 5 in Salford, 3 in Plymouth, 2 in Liverpool, and 2 in Oldham. Small-pox caused no death in any of the twenty-eight great towns. Only one small-pox patient was under treatment at the end of the week in the Metropolitan Asylum Hospitals, and one in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and London Fever Hospitals at the end of the week was 1667, against numbers increasing in the preceding twenty-four weeks from 559 to 1663; 144 cases were admitted to these hospitals during the week, against 132 and 154 in the preceding two weeks. The deaths referred to diseases of the respiratory organs, which had increased in the previous seven weeks from 281 to 432, further rose last week to 552, and exceeded the corrected average by 31. The causes of 103, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Sunderland, Blackburn, and Birkenhead; the largest proportions of uncertified deaths were registered in Oldham, Hull, Liverpool, and Huddersfield.

[1] Eyre & Spottiswoode, East Harding-street, E.C.; Adam & Charles Black, Edinburgh; Hodges, Figgis, & Co., Dublin. Price 6*d*.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the preceding five weeks from 19·8 to 23·9 per 1000, was 23·6 in the week ending Dec. 14th; this rate exceeded by 0·5 the rate that prevailed during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 16·3 and 17·4 in Leith and Perth, to 25·7 in Aberdeen and 26·6 in Glasgow. The 604 deaths in the eight towns showed a decline of 8 from the number in the previous week, and included 20 which were referred to measles, 20 to diphtheria, 16 to whooping-cough, 14 to diarrhœa, 8 to scarlet fever, 7 to "fever" (typhus, enteric, or ill-defined), and not one to small-pox; in all, 85 deaths resulted from these principal zymotic diseases, against 81 and 67 in the preceding two weeks. These 85 deaths were equal to an annual rate of 3·3 per 1000, which exceeded by 1·2 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of measles, which had been, 7, 18, and 11 in the preceding three weeks, rose last week to 20, of which 11 occurred in Glasgow and 8 in Edinburgh. The deaths from diphtheria, which had been 9 in each of the previous two weeks, rose last week to 20, and included 5 in Glasgow, 4 in Edinburgh, 3 in Dundee, and 3 in Leith. The fatal cases of whooping-cough, which had been 21 and 20 in the previous two weeks, further declined, on the other hand, to 16, of which 9 were returned in Glasgow, 3 in Dundee, 2 in Edinburgh, and 2 in Greenock. The 14 deaths attributed to diarrhœa exceeded the numbers in recent weeks, and included 7 in Glasgow and 3 in Dundee. The fatal cases of scarlet fever were fewer by 5 than the number in either of the preceding two weeks; 3 were returned in Glasgow and 3 in Leith. Six of the 7 deaths from "fever" occurred in Glasgow. The deaths referred to diseases of the respiratory organs in the eight towns, which had been 121 and 166 in the preceding two weeks, further rose last week to 167, and exceeded the number in the corresponding week of last year by 64. The causes of 78, or nearly 13 per cent., of the deaths registered in the eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 28·7 and 27·8 per 1000 in the preceding two weeks, rose to 32·2 in the week ending Dec. 14th. During the first eleven weeks of the current quarter the death-rate in the city averaged 26·2 per 1000, the mean rate during the same period being 17·2 in London and 19·6 in Edinburgh. The 218 deaths in Dublin exceeded the number in the previous week by 30; they included 6 which were referred to "fever" (typhus, enteric, or ill-defined), 3 to whooping-cough, 2 to measles, 2 to diarrhœa, and not one either to small-pox, scarlet fever, or diphtheria. Thus the deaths from these principal zymotic diseases, which had been 9, 26, and 21 in the preceding three weeks, declined again last week to 13; they were equal to an annual rate of 1·9 per 1000, the rate from the same diseases being 1·9 in London and 3·1 in Edinburgh. The deaths referred to "fever," which had been 6, 11, and 12 in the previous three weeks, declined again last week to 6; while the fatal cases of whooping-cough, measles, and diarrhœa were almost identical in number with those returned in the previous week. The deaths both of infants and of elderly persons exceeded the numbers in the previous week. Seven inquest cases and 5 deaths from violence were registered; and 68, or nearly a third, of the deaths occurred in public institutions. The causes of 25, or nearly 11 per cent., of the deaths in the city were not certified.

THE BULGARIAN CENSUS.

The last Bulgarian census was taken on Jan. 1st, 1888. the results thereof having only recently been finally published. The population of North and South Bulgaria, as Bulgaria proper and Eastern Roumelia are now styled, had at the beginning of last year a population of 3,154,375 persons. The population of Bulgaria proper was 2,193,434, and of Eastern Roumelia 960,941. The previous census was taken in 1881, at which time the enumerated population of Bulgaria proper was 2,007,919; the increase of population in this portion of the Bulgarian principality in the seven years was 185,515, or rather more than 9 per cent. The

Digitized by Google

movement of population varied very greatly in the different prefectures, owing partly to changes of boundaries; for instance, the population of Sistova appears to have more than doubled itself in the ten years, and that of Lofcha and Varna to have largely increased, while, on the other hand, an actual decrease of population is shown in five of the prefectures, the largest proportional decrease occurring in Vratza and Tirnovo. With regard to the nationality of the population enumerated at the recent census, it is stated that of the population of the entire municipality 2,326,224 were Bulgarians, 607,372 Turkish-speaking Mussulmans, and 58,326 Greeks, leaving a balance of 162,453 described as "various," which included Roumanians, Jews, Gipsies, Slavs of non-Bulgarian race, and Europeans of various nationalities. With reference to these nationality figures it should be pointed out that the Bulgarian population is shown to have increased no less than 16 per cent. during the seven years, while the Mussulman population is said to have decreased by 9 per cent. It may be doubtful whether these figures may have been influenced to some extent by political aspirations; but there would appear to have been, without doubt, a considerable Mussulman emigration in recent years, especially from the prefectures of Tirnovo, Shoumla, Rasgrad, and Plevna. According to the census report the principality contained at the beginning of 1888 six towns having populations exceeding twenty thousand persons; the two largest towns being Philippopolis with 33,032, and Sophia with 30,428. A further list of fourteen towns is given, showing populations ranging between five thousand and twenty thousand persons. The increase of the population of Sophia between the last two censuses in 1881 and 1888 was very nearly equal to 50 per cent. These figures afford evidence of the vigorous vitality of this comparatively new people. It is moreover satisfactory to know that the Bulgarians recognise the value of vital statistics, as evidenced not only by their census report, but by an elaborate report upon the "movement of the population" in the principality during the year 1881, which occupies 1349 pages, but which has only just been issued.

THE SERVICES.

ARMY MEDICAL STAFF.—Brigade Surgeon Saml. Archer to be Deputy Surgeon-General, ranking as Colonel, vice William Cattell, placed on retired pay (dated Nov. 23rd, 1889); Surgeon-Major John Peter Hamilton Boileau, M.D., F.R.C.S. Irel., to be Brigade Surgeon, ranking as Lieutenant-Colonel, vice Samuel Archer (dated Nov. 23rd, 1889); Surgeon Whitley Bland Stokes, M.B., has retired upon temporary half-pay (dated Dec. 1st, 1889); Brigade Surgeon T. Walsh has been appointed Principal Medical Officer on the Staff of the North-Eastern Military District; Deputy Surgeon-General J. Landale has been appointed Principal Medical Officer on the Staff at Cork.

YEOMANRY CAVALRY.—Herts: Lovell Drage, M.B., to be Surgeon (dated Dec. 14th, 1889).

VOLUNTEER CORPS.—*Rifle:* 6th Volunteer Battalion, the King's (Liverpool Regiment): Ernest Wykeham Barnes, Gent., to be Acting Surgeon (dated Dec. 14th, 1889).

VOLUNTEER MEDICAL STAFF CORPS.—The Manchester Division: Surgeon G. H. Darwin resigns his commission (dated Dec. 14th, 1889).—*Infantry:* East London Brigade: Surgeon O. M. White, 1st Tower Hamlets Rifle Volunteer Corps (the Tower Hamlets Rifle Volunteer Brigade), to be Brigade Surgeon, ranking as Lieutenant-Colonel (dated Dec. 14th, 1889).—North London Brigade: Surgeon G. D. P. Thomas, 18th Middlesex Rifle Volunteer Corps, to be Brigade Surgeon, ranking as Lieutenant-Colonel (dated Dec. 14th, 1889).—South London Brigade: Surgeon-Major A. Clark, 4th Middlesex (West London) Rifle Volunteer Corps, to be Brigade Surgeon, ranking as Lieutenant-Colonel (dated Dec. 14th, 1889).—West London Brigade: Surgeon-Major S. P. Smith, 1st Volunteer Battalion, the Royal Fusiliers (City of London Regiment), to be Brigade Surgeon, ranking as Lieutenant-Colonel (dated Dec. 14th, 1889).—Surrey Brigade: Surgeon-Major W. R. Brunton, 1st Surrey (South London) Rifle Volunteer Corps, to be Brigade Surgeon, ranking as Lieutenant-Colonel (dated Dec. 14th, 1889.—Home Counties Brigade: Surgeon-Major W. J. Shone, 1st Bucks Rifle Volunteer Corps, to be Brigade Surgeon, ranking as Lieutenant-Colonel (dated Dec. 14th, 1889).

Correspondence.

"Audi alteram partem."

ACUTE HÆMORRHAGIC NEPHRITIS.

To the Editors of THE LANCET.

SIRS,—I have read with interest the original article in THE LANCET of Dec. 14th by Dr. Crooke and Dr. Nason "On the Occurrence of Acute Hæmorrhagic Nephritis in Suppurative Meningitis," as I have lately had under observation three cases of hæmorrhagic nephritis occurring suddenly in patients suffering from recent acute myelitis, and I have been hitherto seeking an explanation of the phenomenon.

With regard to my first case, I speak from memory, as I have not the notes by me, but I believe Dr. Galloway, the then house-physician, kept a full record of the case. The patient was a middle-aged man, who had been admitted into the hospital about a fortnight before with paraplegia, the result of recent transverse myelitis, when Dr. Galloway drew my attention to the great increase of diuresis that had suddenly occurred (100 ounces per diem), together with hæmaturia. This was very excessive, and the patient soon died. On post-mortem the kidneys were found to be intensely hyperæmic, the medullary portion being almost black.

The second case occurred shortly after in the same ward, and from the notes of Dr. Skyrme, house-physician, I abstract briefly as follows:—W. C——, aged thirty-one, admitted on Oct. 23rd, 1888, with symptoms of transverse myelitis of one week's duration. In this case the state of the urine was noted on admission; it was found normal, reaction acid, quantity about forty ounces in the twenty-four hours. The day after admission 110 ounces were passed. On Nov. 8th a large quantity of blood appeared in the urine; from this date up to Nov. 16th the quantity of urine passed was between seventy and ninety ounces. He lived till Dec. 27th, when he died comatose. The kidneys were enlarged, very hyperæmic, and gave evidence of severe parenchymatous inflammation.

The third case, according to the notes of Dr. Skyrme, house-physician, was a female aged twenty-seven, admitted on Nov. 28th into Rachel ward, suffering from acute ascending myelitis of one week's duration. Urine on admission was about 60 oz. daily, and contained a trace of blood; by daily increases it reached 88 oz. on Dec. 21st, when it gradually diminished till the day of death, Dec. 31st. The amount of blood also increased in amount after admission. The kidneys were similar in appearance to those found in the two other cases. With respect to the causation of the nephritis, I was at first inclined to attribute it to extension upwards of an inflammation of the bladder; but as in the second case the urine was normal up to the onset of the renal symptoms; whilst in the third case—although the hæmorrhage had commenced at the time of admission, I was satisfied there was no cystitis—some other explanation must be sought for. And this I am inclined to think will be found, as Dr. Crooke and Dr. Nason suggest, in disturbance of the vaso-motor system. As an additional support to this view I would point to the remarkable increase in diuresis that occurred in the three cases I have related during the onset of the nephritis.—I am, Sirs, yours faithfully,

Queen Anne-street, Dec. 14th, 1889. CHARLES HY. RALFE.

THE TREATMENT OF CANCER BY ELECTRICITY.

To the Editors of THE LANCET.

SIRS,—Many authorities might be quoted to show that the interruption of strong galvanic currents arrests the heart's action in diastole through the inhibitory action of the stimulated pneumogastric nerve. I am also aware that Ziemssen, by direct stimulation of the heart by strong galvanic currents, increased the frequency of the pulsations, "but to cause a diminution very considerable strength of current is necessary, at least in normal hearts, although it may be different under pathological conditions. It is unnecessary to say that great caution must be used in such experiments."[1] The strength of the currents used to produce these results is not given, but I should think a current of 600 milliampères, as used by Dr. Parsons in the

[1] Erb's "Electro-Therapeutics," translated by Dr. de Watteville, p. 684.

Digitized by Google

treatment of cancer, might be called one of "very considerable strength." "Further than this, it has been ascertained by experiments on animals that even moderate voltaic currents suddenly interrupted could, when applied to the nervous system, cause death; while very much stronger currents applied to other parts of the body were found to be quite harmless in their action."[2] The above paragraph appears in Dr. Parsons' paper in April last[3], but is omitted from the almost identical paper that appeared in a recent number of THE LANCET, probably in consequence of his having since "passed 600 milliampères across the pneumogastric in the neck in a case of Dr. Burton's, and the circulation, if anything, improved." The chief object of my letter, which appeared a fortnight ago, was to try to deter others from attempting Dr. Parsons' mode of treatment, for I still think (and not purely on theoretical grounds) that the operation "is not free from danger to the patients." I cannot acknowledge that the experiment with a solution of iodide of potassium redescribed by Dr. Parsons in his paper in THE LANCET of Nov. 30th "demonstrates in a conclusive way that the passage of a constant current does not cause any decomposition between the poles, although there must of necessity be an exchange of atoms between the molecules," when applied to animal tissue. I do not question the accuracy of his experiment, but in my opinion it does not warrant the conclusion he draws from it. "The exchange of atoms between the molecules" is a theory—the theory of Grotthüss—and may or may not be true. That no permanent and visible decomposition takes place in the interpolar region when a simple electrolyte is experimented on is well demonstrated by Dr. Parsons' experiment, but in my opinion it is not applicable to the human body, which is a mixed electrolyte. The third experiment mentioned in my letter of Dec. 3rd shows that a change can be demonstrated in the interpolar region when a current is made to traverse several heterogeneous electrolytes. The change to which I refer is a decomposition of molecules and recombination of atoms. In the middle cup, in the experiment I have quoted, the sulphuric acid is decomposed and sulphate of barium formed, and that is in consequence of the passage of an electric current and the transportation of ions. The physical questions involved in electrolysis are still so undecided, and are such subjects of controversy among scientific men, and so many different theories have been propounded to explain what takes place in a simple electrolyte, that it would be fruitless at present to try to arrive at a conclusion by any amount of argument as to what does and what does not take place in the passage of an electric current through the human body. From such experiments as I have brought forward showing some of the reactions which actually do take place when an electric current is passed through mixed electrolytes, I have been led to the opinion that probably some interpolar action does take place during the passage of a current through animal tissue.—I am, Sirs, yours faithfully,

Dec. 16th, 1889. W. E. STEAVENSON.

To the Editors of THE LANCET.

SIRS,—In your issue of Dec. 7th Dr. Steavenson takes exception to a statement made by Dr. Inglis Parsons, to the effect that "a constant current does not cause any decomposition between *the poles*." May I venture to suggest that the word "*poles*" is apt to be most misleading, unless one definite and distinct meaning is attached to it when speaking of electro-chemical decomposition. Faraday, who gave to this process the name of electrolysis, also invested it with a suitable nomenclature. He called the substance to be acted on an electrolyte, and the vessel which contains the electrolyte an electrolytic cell. The free ends of the conducting wires of a battery, usually then called respectively positive and negative poles, he termed electrodes, distinguishing them as anode, that by which the current left the battery to enter an electrolyte; and kathode, that by which the current left an electrolyte on its return to the battery. To prevent any confusion of terms, he called the two poles of a battery respectively anelectrode and kathelectrode. Such being the case, I would venture to ask if it would not be advisable to use these names given by Faraday instead of such a vague term as poles, now that the question of the part that electrolysis plays in electro-therapeutics is opening up a large field for discussion. At present we seem to use the term *poles* as signifying either: (1) the terminals of a battery, or (2) the anode and kathode of an electrolyte. Included with the first meaning, we might also enumerate the wires which connect the apparatus applied to the patient, or to the apparatus itself. Now owing to these two different interpretations of the term *poles*, we might be apt to think those in error who use it in a sense different from ourselves. If we refer to the two experiments described in Dr. Steavenson's letter, as performed by Dr. Inglis Parsons and himself, they will help to illustrate my contention. First, I will recall Dr. Inglis Parson's experiment. As an electrolyte, he used a standard solution of iodide of potash, contained in three vessels; the contents of the two outer vessels being made continuous with that of the middle one, by means of the same solution of iodide of potash supported and contained in the interstices of lamp-wick. I would particularly call attention to this fact, as it seems to have been overlooked, and it is of considerable importance in interpreting the experiment. Though the electrolyte was contained in three vessels, yet owing to the way their contents were connected these three vessels and lamp-wick media formed but one electrolytic cell, containing one homogeneous continuous electrolyte, and might be regarded as a curious-shaped cell having three enlarged portions (corresponding to the vessels) and two constricted portions (corresponding to the lamp-wicks) joining them. Such being the case, Dr. Inglis Parsons' statement that decomposition does not take place *between the poles*, is, when applied to his experiment, absolutely accurate, no matter which interpretation we give to the word poles, since there is only one electrolytic cell between the battery terminals, and it is in strict conformity with the law laid down by Faraday, that the liberated ions resulting from electrolysis appear at the electrodes only. But when we come to Dr. Steavenson's experiment, we find then that it makes a great difference as to which interpretation we follow. In his experiment Dr. Steavenson used three vessels, each of which contained a similar standard solution of iodide of potash, but the contents of the three cells were connected by copper wires—that is to say, the homogeneous solution did not form one continuous electrolyte between the battery terminals. Herein lies the difference, for by this means of connecting, Dr. Steavenson created in his experiment three separate and distinct electrolytic cells. A *sine quâ non* for a substance to be an electrolyte is that it be in a fluid form, hence the copper wires form breaks of continuity in the electrolyte. Electrolysis takes place in each vessel, that is to say, in each electrolytic cell, and to quote Dr. Steavenson "free iodine appeared at the positive ends of the pieces of copper wire and a large quantity of gas (hydrogen) at the negative ends." Precisely so. But none appeared at any other parts of his three electrolytic cells. The ions appeared as in Dr. Inglis Parsons' experiment at the electrodes only and not elsewhere. The centre glass vessel in Dr. Parsons' experiment corresponded to the centre of his electrolytic cell; the centre cell in Dr. Steavenson's experiment was a separate electrolytic cell, and in its centre, as in that of Dr. Parsons' single electrolytic cell, no ions were set free.

When now we, looking at Dr. Steavenson's experiment, recall the two interpretations of the term *poles*, I venture to think my contention about this usage becomes plain. If we adopt the first interpretation, that by poles we mean the terminals of the battery or their direct prolongations to the electrolyte, it becomes ridiculous to assert that in his experiment no decomposition took place between the poles. If, however, we use it in the second sense, as meaning the anode and kathode of an electrolyte, then the statement that no decomposition takes place between the poles is in conformity with all known laws of electrolysis. If we used the nomenclature I ventured to suggest, we should, in making our deductions from his experiment, say that electro-chemical decomposition does not occur between anode and kathode, though it does between anelectrode and kathelectrode. These terms may seem clumsy, and therefore not find favour with those accustomed to interpolar as a term; but if interpolar is to be retained when speaking of electrolytical effects, it ought to be qualified so as to definitely show whether it is meant to signify between the poles of a battery or those of an electrolyte between the battery poles. Before concluding, I would like to point out that Faraday noted one liquid could act as anode or kathode to another liquid in contact with it.

[2] Brit. Med. Jour., April 27th, 1889, p. 937. [3] Loc. cit.

Digitized by Google

By floating distilled water on a strong solution of sulphate of magnesia, and passing a continuous current upwards through the two liquids, he found that a layer of magnesia formed at the upper surface of the lower liquid where it touched the water, showing that the water acted as kathode. Since his time Dr. Gore, F.R.S., made a series of experiments, the descriptions of which and his deductions therefrom were published in the Proceedings of the Royal Society for 1881. In these, he states, "that every inequality of composition or of internal structure of the liquid in the path of the current must act to some extent as an electrode."

I venture to think that this should be kept well in mind by those who are studying the place that electrolysis takes in electro-therapeutics. In the animal body, fluids, having inequality of composition or of internal structure, and in contact with one another, exist, and we may reasonably expect them to act as anode and kathode to one another, in the same way that distilled water acted as kathode to the strong solution of sulphate of magnesia. Such being the case when a continuous current passes through an animal tissue, we should surely expect inter (battery) polar decomposition, and know, if we follow the laws of electrolysis, that no inter (electrolyte) polar decomposition can possibly take place. To use the old nomenclature suggested by Faraday: Decomposition may occur between anelectrode and kathelectrode, provided that more than one electrolyte or electrolytic cell be included in the external portion of the battery circuit; but it can take place *only* at the anodes and kathodes and the resulting ions are liberated only there. I am, Sirs, yours sincerely,

Austin Friars, E.C., December, 1889. H. W. D. CARDEW.

COLOTOMY FOR CANCER OF THE RECTUM.

To the Editors of THE LANCET.

SIRS,—This subject has of late attracted so much attention that I think it will interest your readers if I give a brief account of recent experience at the Middlesex Hospital.

Of the inguinal operation I have nothing to say, because it has only lately been performed in one or two cases.

Of 64 cases of cancer of the rectum (males 32, females 32) consecutively under treatment during the seven years from 1882 to 1888, 38 of both sexes were submitted to left lumbar colotomy; of these, 10 died—a mortality of 26·4 per cent. Excision of the rectum was performed in only 4 of these cases, and in 2 cases of cancer of the anus.

Of 18 males who underwent colotomy, 5 died—a mortality of 28 per cent. The causes of death were as follows:—(1) Pyæmia on the twenty-second day after the operation; (2) shock on the day after the operation (in this case the rectum had been excised as well); (3, 4) exhaustion on the seventeenth and twenty-sixth days after the operation; (5) syncope from incessant vomiting, with hæmatemesis, sixteen hours after operation, under chloroform. In 15 cases colotomy was performed to relieve the local disease from irritation by contact with fæcal matter; in the cases that recovered the benefit was very marked, the burning pain and tenesmus previously complained of being in almost every instance completely relieved. Of those who recovered, the average duration of their stay in hospital was thirty-eight days.

Of 14 cases in which colotomy had been performed, the average duration of life, dating from the time when symptoms of the disease were first noticed, was 19·7 months, the longest thirty-nine months: 4 lived from nine to twelve months; 1 from twelve to fifteen months; 3 from fifteen to eighteen months; 1 from eighteen to twenty-one months; 2 from twenty-one to twenty-four months; 2 from thirty-three to thirty-six months; 1 from thirty-six to thirty-nine months.

Of 4 cases in which no operation had been performed, the average duration of life was only 10·9 months, the longest, 24·7 months; 2 lived from three to six months; 1 from nine to twelve months; 1 from twenty-seven to thirty months.

The duration of life subsequently to colotomy in 14 cases averaged 6·5 months, the longest period being twenty-four months; 5 died under one month after the operation; 2 from one to three months; 3 from six to nine months; 1 from nine to twelve months; 2 from twelve to fifteen months; 1 from twenty-one to twenty-four months.

Of 20 females who underwent colotomy, 5 died—a mortality of 25 per cent. The causes of death in these cases were as follows: (1) Syncope under ether during the performance of the operation; (2) shock on the day after the operation; (3) peritonitis on the seventh day after the operation; (4, 5) exhaustion on the tenth and seventeenth days after the operation.

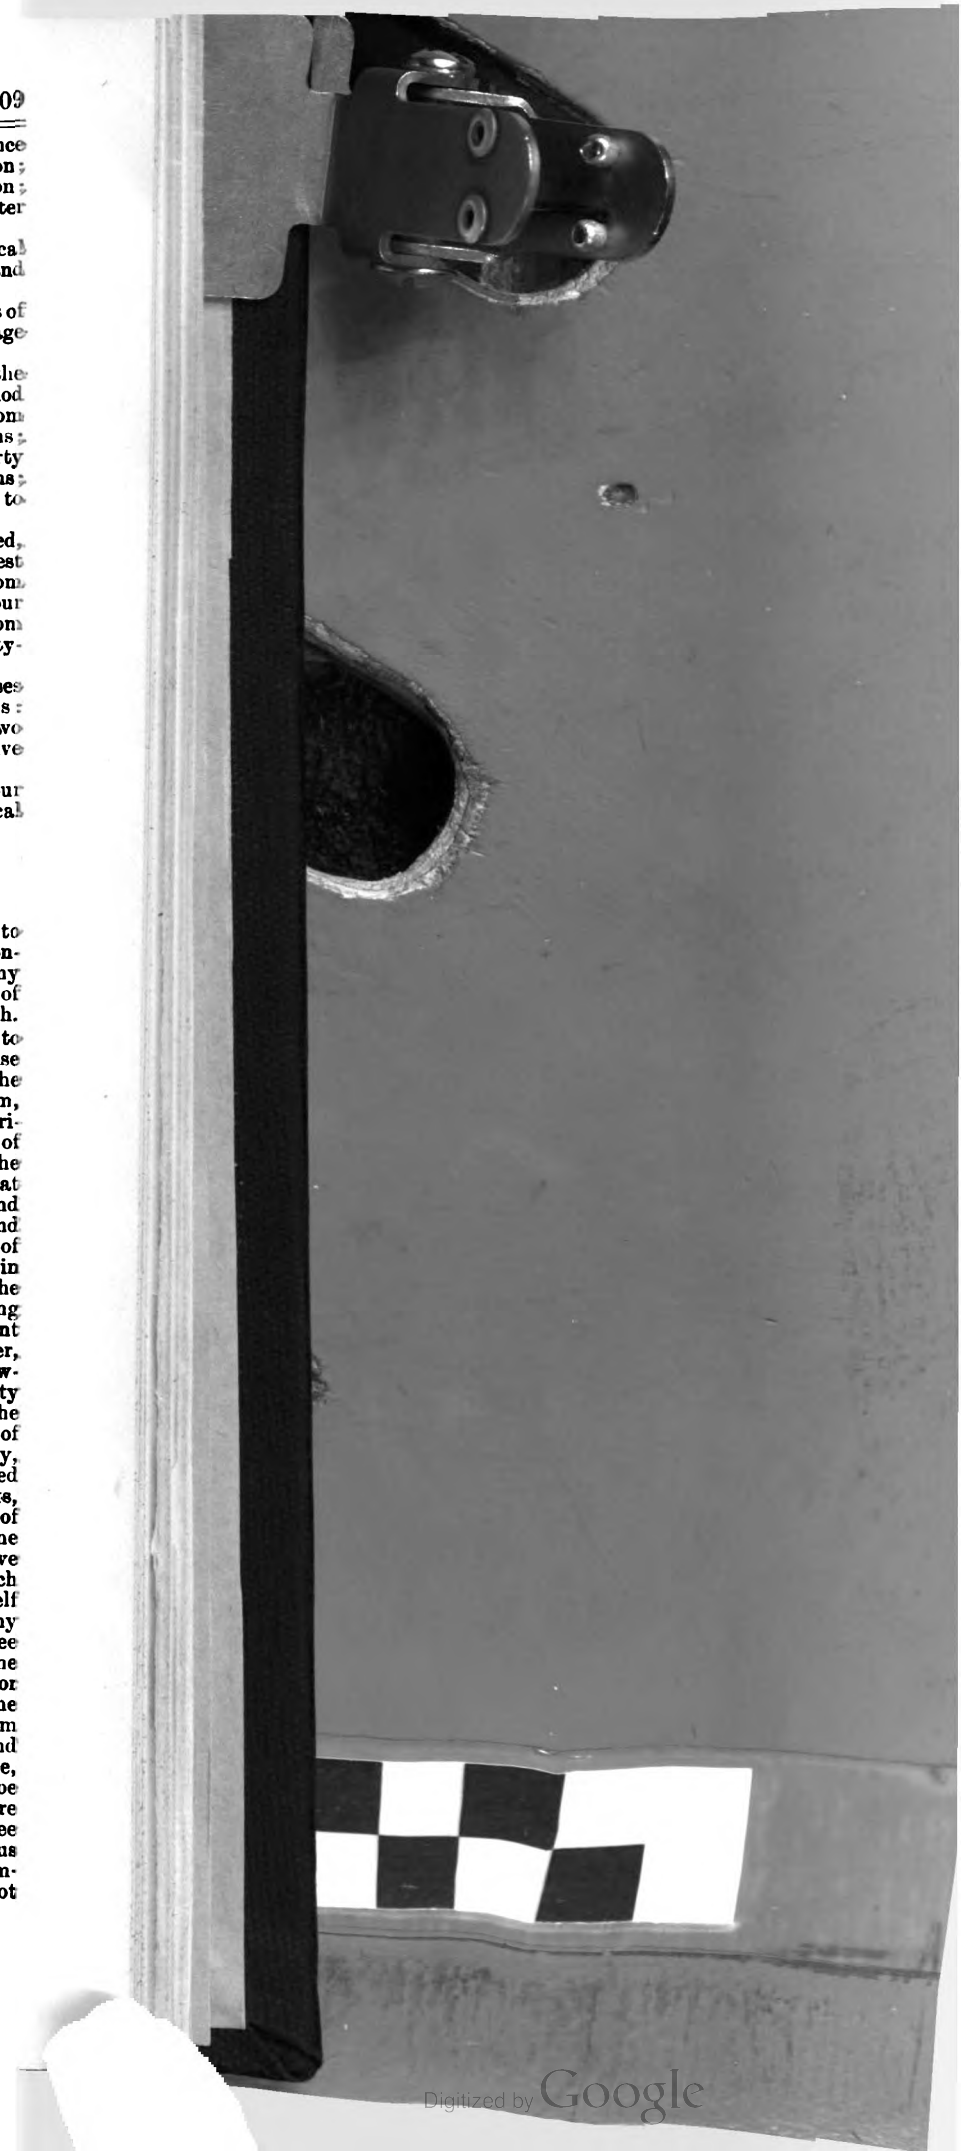
In 15 cases the operation was done to relieve the local disease; here also the benefit as to relief of pain and tenesmus was most marked.

In 5 cases the operation was needed to relieve symptoms of intestinal obstruction. Of those who recovered, the average duration of their stay in hospital was sixty days.

Of 10 cases in which colotomy had been performed, the average duration of life was 29·7 months, the longest period 76·4 months: 1 lived from three to six months; 1 from nine to twelve months; 3 from twelve to fifteen months; 1 from twenty-four to twenty-seven months; 1 from thirty to thirty-three months; 1 from fifty-one to fifty-four months; 1 from fifty-seven to sixty months; 1 from seventy-five to seventy-eight months.

Of 6 cases in which no operation had been performed, the average duration of life was 23·7 months, the longest 39·5 months: 1 lived from nine to twelve months; 1 from twelve to fifteen months; 1 from twenty-one to twenty-four months; 1 from twenty-four to twenty-seven months; 1 from thirty to thirty-three months; 1 from thirty-nine to forty-two months.

The duration of life subsequently to colotomy in 10 cases averaged 6 2 months, the longest period being 33 3 months: 5 died under one month after operation; 1 from one to two months; 2 from six to nine months; 1 from nine to twelve months; 1 from thirty-three to thirty-six months.



For further information on this subject I must refer your readers to the recently published Middlesex Hospital Surgical Report for 1888. I am, Sirs, yours truly,

December, 1889. W. ROGER WILLIAMS.

To the Editors of THE LANCET.

SIRS,—Will you be good enough to allow me space to reply to the criticisms of my colleague, Mr. Jessett, contained in his letter in THE LANCET of Dec. 7th, on my operation for inguinal colotomy for malignant disease of the rectum, which you published in your issue of Nov. 30th.

I accord the "novel method," in contradistinction to "my operation," to my colleague, and again emphasise that I do not wish in any way to detract from him the credit that the idea of this operation emanated from him, and was the outcome of his experience, gained in his experimental work in intestinal surgery on dogs, the report of which he published. With his assistance I performed the operation I described on the three cases "I reported" at the Cancer Hospital on March 2nd, July 30th, and Aug. 6th of this year respectively; two of these cases and the photos of their openings I had the opportunity of showing at the clinical evening of the Medical Society, in conjunction with the one case Mr. Jessett showed. The "novel method" Mr. Jessett described at that meeting and now in his letter differs, he says, in many important particulars from that described by me in my original paper, and he proceeds to mention the points of difference. However, in the one case he brought before the Medical Society he performed the operation (Sept. 28th last) in which the proximal end was cut long and occluded by a piece of rubber band, and the spur removed on the third day, and a remarkably good artificial anus was formed. Aided by the support of a truss he devised to fit the parts, no mucous membrane whatever protruded. The spur of invaginated intestine that Mr. Jessett showed at the same meeting was not removed from the man above alluded to, but from a female, a subsequent case on which he operated (Nov. 8th last), the operation was in itself successful. The report, however, of this case I hope my colleague may give on some future occasion. I quite agree in the dicta laid down by my colleague—viz., "that the bowels should be kept well opened for some three or four days by castor oil or some saline aperient, and the rectum washed out as far as possible once a day with warm water enemata"—a proceeding I thoroughly endorse and always endeavour to have carried out. But if it is possible, and the rectum capable of being relieved, what need be there "yet" for performing inguinal colotomy? More usually, and what actually was the condition in my three cases (reported), the rectum was occluded and impervious by reason of a mass of malignant growth causing complete obstruction of the bowels. Nothing could be got

Digitized by Google

to pass either up or down. Here, then, the operation was urgently called for. In my three cases each were *in extremis;* there were nausea and vomiting, absolute constipation, tongue coated, all appetite lost, and pulse enfeebled, and extreme emaciation; great torture endured in any attempt to obtain an evacuation, which became impossible. The three patients were actually on the point of death. I submit that in these cases the urgency for relief was so great—for, as is usually found, any proposal of operation at an early stage is put off by patients, and their sanction is not obtained until all hopes are given up—that to carry out my colleague's "novel method," and to await a further "four or five" days before an evacuation could be induced or the passing of flatus possible, and little or no food administered, would, in my small experience, jeopardise any chance of recovery for the patient. Although these cases were *in extremis* at the time of operation, all made a good and rapid recovery and increased in flesh, and two now present an admirable appearance; one has since died. I therefore demur that the "novel method" is at all times applicable in advanced cases of malignant disease of the rectum.

I am, Sirs, yours faithfully,

F. A. PURCELL, M.D., M.Ch.

Manchester-square, Dec. 8th, 1889.

DEFECTS IN THE MANCHESTER SYSTEM OF CHECKING OUT-PATIENT HOSPITAL ABUSE.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Dec. 7th you kindly notice the letter of Dr. Harris. You will observe that, as far as checking the abuse of the out-patient department at the Royal Infirmary, Manchester, is concerned, the patients may practically be divided into four classes; (*a*) urgency and accident cases, which are admitted at once without any inquiry; (*b*) those making under the "wage limit," who are also admitted; (*c*) those making *slightly over* the wage limit; and (*d*) those making a considerable wage over it. The latter class *may* be refused first treatment by the surgeon or physician on duty that day. Thus, practically all receive *first* treatment. But there are two very vital errors in the above scheme—first, those who are making slightly over the "wage limit" are allowed to attend at the infirmary for one month, on giving an understanding that they are going to, or have joined, the provident dispensary. Now the entrance-fee to the provident dispensary is sixpence, and the weekly subscription one penny, and benefits are not given until membership has existed for four weeks. Therefore by the above rule, if a man pay a little over sevenpence to the provident dispensary he has the power of demanding relief at the infirmary for four weeks, and can at the end of that time cease payments. Such a rule must be expunged. If the provident dispensary had a *cash* department, then the above condition of affairs could be easily met. But as it now is, the four weeks must elapse before he can participate in benefits. It is therefore to be hoped that not only will the committee of the infirmary allow the above rule to lapse, but that the provident dispensary will not only work the provident but a cash department as well. The second vital error is that a doctor of a provident dispensary has a *right* to send a provident dispensary patient to the infirmary for treatment, and that the infirmary must not ask any questions. Now, the chief objection to such an absurd rule is that the provident dispeusary has most unfortunately dropped its "wage limit," and with the result that many of the provident members are in receipt of wages up to 40*s.* per week. Therefore, although the infirmary "wage limit" is 12*s.* and 18*s.*, the provident member making, say, 40*s.* can compel the infirmary doctors to treat him. It is to be hoped the infirmary committee will rescind this rule. It is a great pity that the provident dispensary ceased working its wage limit of 30*s.* I wish the doctors of the provident dispensaries there would meet together and not only insist on the "wage limit" being reintroduced, but would draw up a scale of fees for cash payments, and for surgical, dental, and obstetric work, and for certificates. It seems to be, though, that in Manchester the abuse of hospitals has only been shifted on to the provident dispensaries, and that no real good can be effected until the provident dispensaries are reformed. As we look to Manchester to show the way, I trust this will soon be brought about. It is well known that a great number of club doctors send their sick members to the charities so as to get rid of them. Is it not to be feared that the doctors of the provident dispensaries do likewise? It is very gratifying to see how this question of hospital reform is coming prominently to the front. It is to be hoped that as a profession we shall soon be able to provide the eight and a quarter millions of the industrial classes of this country with other means of providing themselves with efficient medical treatment than the present medical charities and poor law. That we must have a medical service with two departments—one giving treatment for *cash* payments (such plan as adopted by consultants and advised by the College of Physicians), and the other supplying it on the provident or insurance system—is recognised. The prescribing chemist, unqualified assistant, and that land shark of the medical profession, the bogus club doctor, as well as the one who visits for a *1s.* or *6d.*, and charges *2s. 6d.* for the bottle of medicine—a cross between a chemist and a doctor—have been with us long enough. If we can sink petty trade jealousies and professional rivalry we shall succeed, but if the principle of the majority—"Never mind you, I'm all right"—be adopted, then it must be left to the lay public to legislate for us.

I am, Sirs, yours faithfully,

Liverpool. ROBERT R. RENTOUL, M.D.

THE PREVENTION OF RABIES.

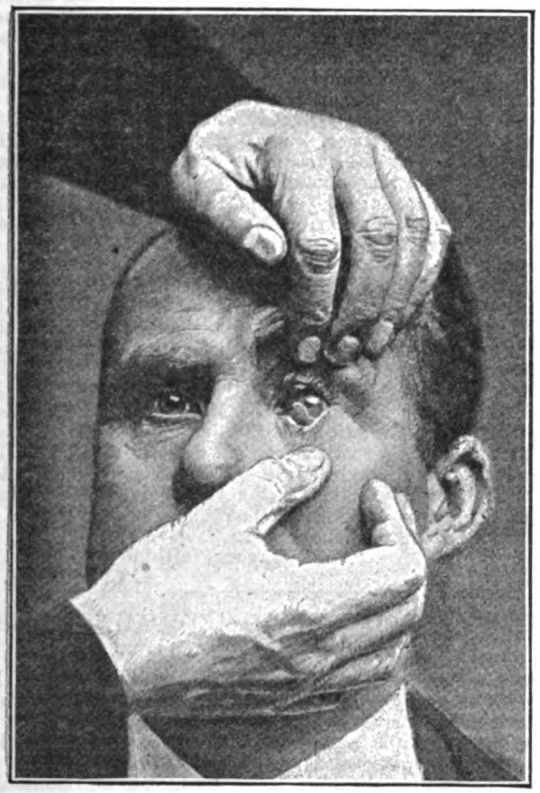
To the Editors of THE LANCET.

SIRS,—The considerable importance of a portion of the subject matter of your leader on the prevention of rabies, which appeared in THE LANCET of Dec. 14th, is undeniable. And it is because of this very importance that I venture to hope that you will allow me to express an opinion contrary to one contained therein. The question of muzzling or not muzzling has unfortunately developed into a duel between the devout Pasteurian and the pseudo-zoophilist, and, more unfortunately still, the stronger adversary is, as I believe, supporting the wrong cause. The supporter of muzzling undoubtedly takes up a strong position. On the one hand, he has a sure and safe therapeusis for the disease; on the other, an unfailing system of prophylaxis. The question of therapeusis it would not become me to discuss, but against the suggested prophylaxis I must enter a strong protest. It is claimed that by a universal muzzling, applied for a limited time and followed by a strict quarantine, rabies would be stamped out for ever, so far as these islands are concerned. In the first place, and allowing that a universal muzzling is practicable, this doctrine assumes that rabies is a specific, an unalterable disease; that it always was rabies and will be rabies for evermore, or at any rate until eradicated by the muzzling process; and, further, that if all the *materies morbi* of rabies now in existence could be destroyed, the disease would never appear again. Against this view of the matter Pasteur's system of treatment affords a strong argument. It is claimed that by successive cultivations the *materies morbi* undergoes certain changes—in other words, that it obeys certain laws of evolution. If it obeys these laws in the laboratory, it must be allowed to obey them outside. That being so, rabies cannot be said to be a specific disease—at least not in the sense in which the word "specific" is generally used. It follows, then, that if it were possible to eradicate all the *materies morbi* of rabies which existed at a given time, we should have no guarantee that the disease would not appear again in the future, as it must have done in some time past. Leaving, however, this somewhat abstract view of the matter out of the question, there is a nearer and more practical point to be considered: that is, Is muzzling likely to lower to any appreciable extent the present annual mortality from hydrophobia? At the outset it is noticeable that, whilst the muzzling order now in force in certain localities carefully provides for the muzzling of dogs which have not got rabies, it affords a remarkably inefficient protection against those which have; for under the order the dog is only muzzled for the hour or two out of the twenty-four during which he happens to be out of doors. Hence the chances are about twelve to one that the dog will not have his muzzle on when the disease first manifests itself, and he certainly will not wait then to have the muzzle applied before he starts on his rabid career. It seems to have been overlooked, too, that a far sterner and more scientific method of prophylaxis against rabies has long been in force: that is, as soon as a dog shows signs of rabies it is promptly killed. What more thorough system of prophylaxis could possibly be adopted? Take the human

Digitized by Google

subject, for instance. The most thorough sanitarian would probably look forward hopefully to the result if every person who had contracted, say, syphilis were at once treated with euthanasia. Yet, on the face of the fact that every dog who shows signs of rabies is killed at once, we are told that the number of cases of hydrophobia in the human subject is on the increase. It seems, then, absurd to suppose that the desired result is likely to be attained by the simple process of muzzling for a few hours of the day those dogs which have not yet had the disease.

I am, Sirs, yours obediently,



Chatham, Dec. 18th. ALEX. G. R FOULERTON.

*** Our correspondent has overlooked the fact that in certain countries where "muzzling" is generally enforced, rabies is practically absent—e. g., Germany.—ED. L.

THE TREATMENT OF SYMBLEPHARON.

To the Editors of THE LANCET.

SIRS,—*Apropos* Professor Snellen's (Utrecht) paper on symblepharon recorded in your recent report of the proceedings of the Ophthalmological Society, will you allow me to remark that the best method of dealing with such cases of extensive destruction of ocular and palpebral conjunctiva is by the transplantation of skin *en masse* without pedicle on to the surface of the eyeball itself? I have spoken of this operation elsewhere, and the accompanying photograph of a very bad case, occasioned by the impact of a piece of molten metal, treated in this way may be taken as evidence of the very pleasing results it is possible to attain. The patient, whose left lower lid was firmly adherent to the

globe when I first saw him, was injured while working at the Codnor-park Ironworks in this neighbourhood, and as there was no conjunctiva which could be utilised, I transplanted a piece of cuticle (two inches by one inch) from the upper lid of the right eye on to the surface of the left globe, where it may be seen in white outline in the photograph. The upper lid of the left injured eye, which was strongly incurved owing to excoriation of its under surface at the time of the accident, was treated by a method of skin transplantation (shown in the photograph) with pedicle, which I have already illustrated in your pages, and the eye is now quite free, the sight perfect, and the patient naturally very pleased at his unexpected and complete recovery.

With regard to the method described by my friend, Professor Snellen, I may remark that it has been said that "there is nothing new but that which has been forgotten," and it is certain that I devised and frequently practised precisely the same method of skin transplantation with pedicle through a button-hole in the lid at least ten years ago. Indeed, it is upwards of that time since I introduced a patient who had been treated in this way to the notice of the members of the Clinical Society of London, and those of your readers who care to do so will find a report of the case in the Transactions published by that association. It is obvious, however, that, when the vitality of the flap can be preserved (and my experience has demonstrated that there is little or no difficulty in doing so), my more recent method of transplantation of skin *en masse* without pedicle is vastly more convenient and efficacious.

I am, Sirs, your obedient servant,

CHARLES BELL TAYLOR, M.D.,

Nottingham, Dec. 9th, 1889. Surgeon to the Eye Infirmary.

THE LATE PROFESSOR BOYES SMITH, M.D., F.R.C.P.: AN APPEAL.

To the Editors of THE LANCET.

SIRS,—It is seldom that an appeal for help is called for on behalf of the widow of a medical officer of H.M. Indian Army. A painful exception to this rule has now to be brought to the notice of the retired brother-officers of the late Dr. Boyes Smith, of the Bengal Army. They will be surprised and grieved to learn that his widow and little girl, six years of age, have been left, to put it plainly, with £60 a year. Dr. Smith, as a single man, indulged a generous disposition in helping others who were in reduced circumstances, and sustained pecuniary losses in other ways. He married after retirement from the service, and could not by the rules of the Military Pension Fund become a subscriber to that fund on behalf of his wife and child. After a distinguished career in India, both in the military and civil branches of the medical service, Dr. Smith was appointed to the chair of Military Medicine in the Army Medical School, and was cut off by cerebral disease before he could "redeem the time" and make something like an adequate provision for wife and child. The case has been warmly taken up by the *Indian Medical Gazette*, and a subscription list has been opened in its pages. It is hoped that the retired brother-officers of the late Dr. Smith will assist their old friends in India to rescue his widow and child from a condition, considering their former position, little short of want.

Messrs. Grindlay and Co., 55, Parliament-street, S.W., are authorised to receive subscriptions and give acknowledgments.—I am, Sirs, yours faithfully,

W. CAMPBELL MACLEAN, M.D., LL.D.,

Surgeon-General, late Professor of Military Medicine,

December, 1889. Army Medical School.

INFLUENZA.

To the Editors of THE LANCET.

SIRS,—For some months there has been an epidemic of influenza, which has not, however, been confined to this neighbourhood, as I have had patients from places so far apart as Edinburgh, Bournemouth, Southampton, and from the more central parts of London. The symptoms have varied in intensity, the temperature rising in four cases as high as 105°, but falling within times varying from twenty-four to sixty hours to normal or sub-normal. In most of the cases of any severity there has been marked cerebral disturbance, the patients expressing a fear that they were "going mad." In the milder cases there were depression of spirits, anxiety, fear of some calamity, in nearly all nausea or vomiting, and in many violent diarrhœa, sore-throat with extreme muscular weakness, and cardiac pain and depression, and severe aching of the limbs and muscles of the back, about complete the catalogue of symptoms. One of the worst attacks (temperature 105·4°) occurred in a woman three days after parturition, and I should have expected she was going to have puerperal fever; but, having seen so many of these cases, I thought it would prove to be influenza, and she is now convalescent. I have, after considering the symptoms and histories of the various patients, come to the conclusion that it has been caused by the very high temperature which

Digitized by Google

has prevailed since the fall of the leaf this year, which has caused rapid decay of the soft part of the leaves, which usually takes place slowly in the low temperature of autumn, and has caused an unusual development of the malarial poison which causes ague in temperate climates, and the tropical fevers which attack those living in the influence of tropical forests, like the jungle fever of India and the fever of which Stanley and Livingstone give us such graphic accounts. I have found antipyrin and salicylate of soda the most useful remedies.—I am, Sirs, yours truly,

South Tottenham, Dec. 1889. GEO. B. BEALE.

To the Editors of THE LANCET.

SIRS,—It may be of advantage to some practitioners to know that there is a substance perfectly harmless in use, which has the effect of *immediately* lessening, if not altogether putting an end to, the most pronounced *nasal* symptoms of acute febrile catarrh. One application is generally sufficient for an ordinary "cold in the head." Powdered "periodate crystals" (Weaver's) forcibly blown into the nostrils, or simply dropped in, if the patient is lying flat on his back, and then sniffed up, will cut short an attack, if administered *at the very beginning*. The combination of bismuth, morphia, and gum-powder, in the form of "snuff," once commonly used, is valueless when compared with "periodate," which is, as far as is at present known, the most powerful antiseptic ever used. It can be swallowed in almost any quantity without the least risk.

I am, Sirs, yours truly,

Dec. 11th, 1889. BERNARD O'CONNOR, M.D.

OPERATIVE TREATMENT OF FLAT-FOOT.

To the Editors of THE LANCET.

SIRS,—Mr. Hare pronounces my plan of treatment to be unsuited to *extreme* cases—whatever I may think, I did not say that it was,—but he ignores my objection to osteotomy as not justifiable in his reported case, as to which I had said that I did not regard it as *extreme*. It was so headed in the paper, but I hold that the description proved it to be not even a case of *complete* flat-foot. It is impossible that the great toe can be held flat on the ground, as shown, unless the short muscles of the sole be in active condition. These, in complete flat-foot, are paralysed by pressure. The footprint, too, shows that the cuneiform bone had not fallen, and that the astragalus did not project beyond a line drawn from the inner margin of the heel to that of the metatarso-phalangeal joint. The whole case, as it seems to me, is described with striking fidelity to life although wrongly titled. A lad, of previously "active habits," during ten months was subjected to unduly prolonged standing. He wore "canoe-shaped" boots, whose fault was, not that they were "pliable, giving no support to the arch," but that they distorted the great toe. By this the second was so persistently elevated that it remained so, giving no mark in the footprint. The great toe, unable to move in its natural plane (downwards and inwards), suffered irritation at the metatarsal joint and so ceased to move. The bow-string or tie-rod action of the long flexor was thus lost and the arch gave way. The right foot was most affected because on it the body rested in the stand at-ease position. The joint mentioned was painful also because (being the anterior pillar of the arch) the weight of the body came plump upon it every time the heel was raised. In healthful activity it is relieved by the action of the long flexor causing it to dance (as I express it in "The Human Foot") on the tight-rope, formed by the tendon. This happens as the heel, every time of raising, is drawn towards the great toe as a fixed point.

The best treatment of such a case as Mr. Hare's is to let the patient, for a time, live with bare feet, moving freely his feet and toes without the weight of the body on them. He should then, always with bare feet, and in the four-square position, move freely to and from tiptoe as much as he can. Had Mr. Hare's patient done this I am confident that he would have recovered functional activity in less time than it took him to recover from the operation. That the bone surfaces had been in ten months so "profoundly altered in shape" as to justify destruction of the most important joint in the tarsus I cannot believe. My first protest against such a proceeding was recorded in THE LANCET of Feb. 9th, 1884, in support of the editorial opinion that Professor Ogston's operation could only rarely be warranted. I ask leave to emphatically repeat it now. The principles which, as I think, should guide the treatment of flat-foot are set out at length in the forthcoming number of the *Edinburgh Medical Journal*.

I am, Sirs, yours faithfully,

Gloucester, Dec. 14th, 1889. T. S. ELLIS.

"MEAN DURATION OF LIFE."

To the Editors of THE LANCET.

SIRS,—The subject matter of actuaries' inquiries is the present value of sums of money payable at death or at intervals during life, and for this purpose the figures of the Life Table (the sum of which shows the "mean duration of life") are combined by them with the figures of a Discount Table previously to summation; and further, the Life Table generally used by actuaries commences at ten years of age, and thus gives no information as to mean duration of life. These are sufficient reasons why actuaries should not affect the expression "mean duration of life." Parkes's formula, quoted by Dr. Lyon, aims at ascertaining the mean duration of life by a correction applied to the reciprocal of the death-rate; whereas the class of formulas to which I alluded in my previous letter aim at ascertaining the reciprocal of the mean duration of life by a correction applied to the death-rate itself. I think Dr. Lyon will find that the following formula fits Dr. Corfield's figures pretty closely:—

Death-rate × ·5634, *plus* birth-rate × (1 − ·5634) = C,
1000 ÷ C is taken as the "mean duration of life."

As to the reason why the particular constant ·5634 has been chosen, or the grounds on which the result should be taken as an approximation to the mean duration of life, I can make no suggestion; I merely indicate the method which has apparently been used. Dr. Lyon's assertion, that "the expression 'mean duration of life' applied to any particular year is scientifically meaningless and misleading to the public," is somewhat sweeping. It must be admitted that social orators have too often misled the public by a misuse of the expression; but, for all that, it has a definite scientific meaning, and, moreover, the mean duration of life is the best measure of health conditions that has yet been devised in the form of a single number; provided only that such a period is chosen that the years of life shall be sufficient to give fairly trustworthy death-rates at the various ages. The difficulty in the way of its general use is the labour of calculating it.

I am unable to follow Dr. Lyon's objection that this number is "essentially yearless, and quite unfit to be employed as a test of health in a particular year." On the contrary, I should say that the mean duration of life, deduced from the rates of mortality in any year, belongs essentially to that year, and is simply and only fit to measure the state of health in that year. If Dr. Lyon's objection applies only to the term itself, an explanatory form, such as follows, may possibly recommend itself to him:—The mean duration of life which *would be attained* if the rates of age-mortality observed in the year remained constant. Surely it cannot be disputed that this is a fair measure of the combined effect of those rates.

I am, Sirs, yours faithfully,

Dec. 14th, 1889. A. C. WATERS.

THE PROPOSED "PUBLIC MEDICAL SERVICE."

To the Editors of THE LANCET.

SIRS,—I am sorry that my reply last week to Dr. F. Taylor and Dr. Hugh Woods was too long for publication, and was afraid it might be so when I wrote it.

On the 12th inst. a meeting of the Metropolitan Counties Branch of the British Medical Association was held in Jermyn-street for the purpose of discussing Dr. Rentoul's scheme. Dr. Ord presided, and Mr. John Page Hentsch, a non-member of the Association, after addressing the meeting, requested a member to propose for him his resolution: "That this meeting considers Dr. Rentoul's scheme to be impracticable, and that, even if practicable, it would be disadvantageous to the great bulk of the general practitioners." Mr. Campbell Boyd proposed and Dr. Richard Paramore seconded this resolution, and it was carried by an overwhelming majority. I am informed upon good authority that, although so many branches of the Association have rejected Dr. Rentoul's scheme, a certain number of the officials of the Association, some of whom are on the Council

Digitized by Google

of the Metropolitan Provident Medical Aid Association, with the general practitioners, and would therefore suggest that the Association should take the matter up, and endeavour to correct this injustice, for the purpose of giving the scheme a fair trial.

Stockwell-road, S.W., Dec. 16th, 1889. H. E. CARPENTER.

PRIMARY TUBERCLE OF THE KIDNEY.

To the Editors of THE LANCET.

SIRS,—Mr. J. Knowsley Thornton, in his lecture delivered at the Royal College of Surgeons, on Dec. 12th, 1889, and published in a lately issued number of THE LANCET, has drawn attention to the fact that primary tubercle of the kidney is sometimes overlooked, and that the symptoms are attributed to other causes, such as stone in the bladder, to stone in the ureter, to calculous disease, to malignant disease of the kidney, to cystitis, to pyelitis, to pyelo-nephritis, to nephritis, to nephritis with suppuration, to nephritis with calculus, to tubercle of the bladder, to tubercle of the kidney, to tubercle of the kidney and bladder, to tubercle of the kidney and ureter, to tubercle of the kidney, ureter, and bladder, to tubercle of the kidney, ureter, bladder, and prostate, to tubercle of the kidney, ureter, bladder, prostate, and testicle, to tubercle of the kidney, ureter, bladder, and testicle, to tubercle of the kidney, ureter, and testicle, to tubercle of the kidney and testicle, to tubercle of the testicle, to tubercle of the prostate, to tubercle of the prostate and testicle, to tubercle of the bladder, prostate, and testicle, to tubercle of the bladder and testicle, to tubercle of the bladder, ureter, and testicle, to tubercle of the bladder, ureter, prostate, and testicle, to tubercle of the ureter, to tubercle of the ureter and testicle, to tubercle of the ureter, prostate, and testicle, to tubercle of the ureter, bladder, and testicle, to tubercle of the ureter, bladder, prostate, and testicle, to tubercle of the ureter, kidney, and testicle, to tubercle of the ureter, kidney, prostate, and testicle, to tubercle of the ureter, kidney, bladder, and testicle, to tubercle of the ureter, kidney, bladder, prostate, and testicle, to tubercle of the ureter, kidney, and bladder, to tubercle of the ureter, kidney, bladder, and prostate, to tubercle of the ureter, kidney, prostate, and bladder, to tubercle of the ureter, prostate, and bladder, to tubercle of the ureter, prostate, bladder, and testicle, to tubercle of the ureter, prostate, bladder, testicle, and kidney, to tubercle of the ureter, prostate, testicle, and kidney, to tubercle of the ureter, testicle, and kidney, to tubercle of the ureter, testicle, kidney, and bladder, to tubercle of the ureter, testicle, kidney, bladder, and prostate, to tubercle of the ureter, testicle, prostate, and kidney, to tubercle of the ureter, testicle, prostate, kidney, and bladder, to tubercle of the ureter, testicle, prostate, bladder, and kidney, to tubercle of the ureter, testicle, bladder, and kidney, to tubercle of the ureter, testicle, bladder, kidney, and prostate, to tubercle of the ureter, testicle, bladder, prostate, and kidney, to tubercle of the ureter, testicle, bladder, prostate, kidney, and testicle, to tubercle of the ureter, testicle, bladder, kidney, and testicle, to tubercle of the ureter, testicle, bladder, kidney, prostate, and testicle, to tubercle of the ureter, testicle, bladder, prostate, kidney, and testicle, to tubercle of the ureter, testicle, bladder, prostate, and kidney, to tubercle of the ureter, testicle, bladder, and prostate, to tubercle of the ureter, testicle, prostate, and bladder, to tubercle of the ureter, testicle, prostate, bladder, and kidney, to tubercle of the ureter, testicle, prostate, kidney, and bladder, to tubercle of the ureter, testicle, kidney, and bladder, to tubercle of the ureter, testicle, kidney, bladder, and prostate, to tubercle of the ureter, testicle, kidney, prostate, and bladder, to tubercle of the ureter, testicle, kidney, prostate, bladder, and testicle, to tubercle of the ureter, testicle, kidney, bladder, prostate, and testicle, to tubercle of the ureter, testicle, kidney, bladder, and testicle, to tubercle of the ureter, testicle, kidney, and testicle, to tubercle of the ureter, testicle, prostate, and testicle, to tubercle of the ureter, testicle, prostate, bladder, and testicle, to tubercle of the ureter, testicle, prostate, kidney, and testicle, to tubercle of the ureter, testicle, prostate, kidney, bladder, and testicle, to tubercle of the ureter, testicle, prostate, bladder, and kidney, to tubercle of the ureter, testicle, prostate, kidney, and bladder, to tubercle of the ureter, testicle, kidney, and bladder, to tubercle of the ureter, testicle, kidney, bladder, and prostate, to tubercle of the ureter, testicle, kidney, prostate, and bladder, to tubercle of the ureter, testicle, kidney, prostate, bladder, and testicle, to tubercle of the ureter, testicle, bladder, and kidney, to tubercle of the ureter, testicle, bladder, kidney, and prostate, to tubercle of the ureter, testicle, bladder, prostate, and kidney, to tubercle of the ureter, testicle, bladder, prostate, kidney, and testicle, to tubercle of the ureter, testicle, bladder, kidney, and testicle, to tubercle of the ureter, testicle, bladder, kidney, prostate, and testicle, to tubercle of the ureter, testicle, bladder, prostate, and kidney, to tubercle of the ureter, testicle, bladder, and prostate, to tubercle of the ureter, testicle, prostate, and bladder

vessels, 362 foreign steamers, and 348 foreign sailing vessels. On the principle that prevention is better than cure, much good was done in inspecting the ships and insisting on necessary alterations, which were all complied with, with the exception of six vessels, which went away before they could be revisited.

University of Durham.

At the Convocation of the University of Durham, held last week, the papers report that the restrictions as to the admittance of undergraduates having been removed, they mustered in strong force, and with the outside flank of the medical men from Newcastle succeeded by their enthusiasm in restoring a good deal of the humour and good nature which has for many years been introduced to academic meetings of this kind.

Death of Dr. E. P. Mead of Whitby.

I regret to notice the death on the 7th inst., of Dr. E. P. Mead, at his residence in Whitby, Yorkshire, where he was a well-known and active practitioner for about thirty-five years. Dr. Mead, who was a native of Whitby, studied and graduated in Edinburgh, and, commencing practice in Whitby at a very opportune period, soon attained a large measure of success, which amidst many changes he never lost. His manners were attractive to patients, while he was extremely kind and considerate. He never tried to do more work than he was able to do well—that is, he never burthened himself with public or professional appointments, and thus no doubt had often more time to do himself and his patients justice. Dr. Mead, whose age was fifty-nine, began to fail in health about twelve years ago. After some rest and continental travel he returned home much improved, though afterwards he began to suffer from asthma and the painful passage of gall-stones. On Wednesday, the 4th, he was seized with one of these attacks, which returned on the following day and on the Friday, producing syncope, when death soon followed. He was attended by his son, who is in the profession at Whitby, and by Dr. Stewart and Mr. Stonehouse. Dr. Mead has left a large family. Another son, Dr. Rivis Mead, is practising in Australia; and a few months ago I recorded the distressing death of Dr. Mead's second son, a fine young man, who was mate on board a Tyne steamer, but who, in the delirium of fever, escaped from his attendants, and leaping overboard was drowned. Dr. Mead's funeral was largely attended, as he was a favourite with all classes; indeed, the town might be said on that day to be in mourning.

Darlington.

A dentist here met with a rather curious accident the other day. He was asked to go to the infirmary to reduce a dislocated jaw, but in the reduction, the teeth snapping on his fingers, he received some very unpleasant wounds, followed by blood poisoning. Fortunately he was insured in an accident company, who met the claim.

Newcastle-on-Tyne, Dec. 17th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

EDINBURGH.

The Universities Commission.

IN anticipation of the meeting of the Universities Commissioners in January next, there seems to be a very general flutter and activity in the "cots" of those who think that they will be in any way affected by the decisions. One hears of very little else just now; it is the sole topic of conversation in medical teaching circles, and all the arrangements and appointments in the colleges and in the schools are made with a view to what has to be brought up before the Commission. The Colleges of Surgeons and Physicians have both appointed committees and sub-committees, whose duty it is to prepare evidence, examine past legislation, and recommend what action shall be taken by the Colleges. The University authorities have also been asked, or will be asked, to prepare statements and offer suggestions or evidence for the consideration of the Commission, so that all these bodies will be adequately represented. The lecturers in the Extra-mural Medical School are also conferring amongst themselves, and, from what has leaked out as to the results of their deliberations, there seems to be a strong leaning on the part of the majority of the extra-mural teachers towards free trade in both teaching and examining. It is probable that some of these matters will be spoken of at the College of Physicians' annual dinner, which takes place on Thursday, so that if any of the Fellows of the London College are present they may hear in private what is never reported to the public. Those first in the field with any public reports of their proceedings are the students' Representative Councils of Edinburgh and Glasgow. The Edinburgh committee report that they are prepared to advise that the following, amongst other points, be raised and pressed before the Commission: that a Faculty of Science should be created in Edinburgh University; that the course in medicine extend over a curriculum of five years; that there should be a short preliminary course in medicine and surgery before the courses usually taken; that there should be short compulsory courses on diseases of the eye and ear, for which the fee should not be more than one guinea; that there should be a matriculation examination for all students entering the University with a view to graduation, and that at least four compulsory subjects in that examination be passed at one time. If the other bodies go to work in the same business-like fashion as the Students' Representative Council has done, it may be anticipated that the work of the Commissioners will be very much less arduous than they could at one time hope to be the case. There are many other matters that the students might take up, but they prefer to rest content with indicating the general lines on which they think that reform should take place.

The Royal Asylum at Morningside.

It is a matter for some congratulation that the Craiglockhart Hills question has at length been satisfactorily and amicably settled. It was pointed out in the columns of THE LANCET at the early part of this year that it would be a great boon to the asylum and its patients, and very little, if any, loss to the community, if certain lands were taken in exchange for part of Easter Craiglockhart Hill. This opinion was maintained and endorsed by Professor Sir Douglas Maclagan, Dr. Sibbald, and others. It has now been decided by the Parochial Board authorities to hand over ten acres and a quarter of the Easter Hill, "which from its contour and situation is of no great value for recreative purposes," and to take in return from the asylum trustees nine acres and a quarter of valuable arable land, which will in all probability become more and more valuable as the city boundaries extend. The splendid asylum buildings, of which a short account appeared at the time the plans were submitted, can now be completed.

The Royal Society.

At the meeting of the Royal Society held last night, Sir Arthur Mitchell, M.D., presiding, two papers of considerable medical interest were read: the first, by Dr. Ashdown, "On the presence of certain Substances in the Urine that reduce Oxide of Copper in the presence of an Alkali"; the second, by Dr. G. E. Cartwright Wood, "On Enzyme Action in the Lower Organisms."

The Health of the City.

In presenting the monthly reports of the medical officer of health of the city, Baillie Dr. Russell called attention to the fact that the death-rate for the past month was slightly higher than that for November of last year, and than the average for the last five years. This was accounted for chiefly by an outbreak of measles in the Old Town, and was confined mainly to children under five years of age. There were at present 204 patients in the City Hospital.

New Entries in the University of Edinburgh.

Up to Dec. 2nd 340 first-year medical students had entered in the University of Edinburgh, of whom 140 began their studies last summer session.

Edinburgh, Dec. 17th.

GLASGOW.

Social Problems in Glasgow: Housing of the Poor.

On Nov. 6th last, Dr. J. B. Russell, on retiring from the Presidentship of the Glasgow Philosophical Society, gave another of those addresses which have perhaps done more than anything else to stir up in the people of this city a sense of their responsibility with regard to the wretched condition of the very poor in our midst. There are few who have access to such sources of accurate statistical

Digitized by Google

information as are open to Dr. Russell, and fewer still are they who have the ability to interpret such masses of figures in a way which will appeal with any force to the conscience or rouse the sympathies of the community. It is not easy to epitomise such an address, so full is it of facts, and throughout of such interest. It is "an object lesson in sanitation and social economics." Premising that the notorious District 14 of Glasgow is not now worse than it has long been—that, in fact, it has been "the heartbreak of successive generations of Glasgow philanthropists,"—Dr. Russell gives a number of very startling facts regarding it for the year 1888. It embraces an area of thirty-five acres, in which there are 1308 houses, inhabited by 7150 persons. This is ·57 per cent. of the total area, inhabited by 1·29 per cent. of the total population of the city. Contrasting this with the healthiest district of Glasgow, District 17, we find that the latter embraces 10·24 per cent. of the area and only 5·62 per cent. of the population. Fifty-one per cent. of the houses are "ticketed," and are thus subject to night inspection for the prevention of overcrowding. In 1888 there were 232 deaths and 218 births, so that this district produced 14 fewer lives than it consumed. Reduced to rates per 1000 of the population, its birth-rate was 30·49, its death-rate 32·45; of children under one year the death-rate was 239 per 1000. As regards illegitimacy, 25 per cent. of the children were born out of wedlock; or, to put it otherwise, 1·29 per cent. of the population of the city contributes 3·7 per cent. of the total illegitimacy of the city. The details of the mortality are interesting:—Zymotic diseases (including diarrhœa), 4·76 per 1000; nervous diseases and diseases of nutrition in children, 3·36; acute diseases of the lungs and consumption, 14·68; miscellaneous unclassified diseases, 9·65—total, 32·45. It is thus obvious that infectious diseases and diseases of the lungs are the two scourges of District 14. The death-rate here from diseases of the lungs alone is greater than the death-rate from all causes in District 17. In District 14, 41 per 1000 of the children born died because they were born prematurely—a fact which furnishes a good gauge of the deadly influences to which children are exposed both after birth and during intra-uterine life; 18·5 per cent. of all the deaths in District 14 were uncertified. In 15·5 per cent. of the fatal cases it was alleged to the Registrar that there had been absolutely no medical attendance during the last illness. Forty per cent. of those who died were enrolled in friendly societies; in the Springburn district, a good working-class locality, 70 per cent. are so enrolled. District 14 is therefore not distinguished for providence. Of the 232 deaths, 18·5 per cent. were uncertified, 29·7 per cent. died in public institutions, and 51·8 per cent. at home. Of those who died in public institutions, the cost of treatment of 25·4 per cent. fell on the public rates; that of the remainder, 4·3 per cent. of the whole, fell on the various charitable institutions. Basing his opinion on these and other facts, Dr. Russell thinks that "the probability is that very little medical aid is obtained in this district except what the public pay for or the profession bestow for nothing." Of those who died in this district, the cost of interment was borne by the ratepayers in 37 per cent. of the cases. Of the children born, 55 per cent. began their lives either at the cost of charity or of the rates; 50 per cent. of the children born were vaccinated gratuitously. Such a district must inevitably make enormous demands upon the services of the sanitary department; in 1888 no fewer than 16,529 separate visitations and inspections were made in it, and behind all this there was a proportionate amount of office work and money expenditure. With regard to the work of the Police Department in District 14, this district is still "the Alsatia of Glasgow"; it furnishes the greater part of the work of the Central Police Court. The privy system in the district is abominable, and such as to encourage filthy habits. Though there are 1308 houses and 7150 people, there are only 105 w.c.'s in the whole district. The last bit of information given by Dr. Russell is curious and very instructive—namely, a return of the rental of the licensed premises in District 14, as compared with the rental of premises where food alone is sold: the former amounts to £5167 2*s.*, the latter to £4944 12*s.* It is to be noted, as making this statement still more striking, that the rental of the Public Fish Market (£1000), which supplies the whole city and surrounding parts, is thrown in with the rental of houses where food but no "drink" is sold. District 14 thus spends as much in the luxury of drink as in necessary food. "I think, as honest business men, apart from all views as to total abstinence or the association of crime, immorality, and disease with excess in the use of alcohol, you will agree with me in thinking that people who do not pay their rates, who throw themselves on the legal and charitable resources of the public in their sickness, their birth, death, and burial, simply take from the pockets of the public every sixpence which they spend on drink." Dr. Russell mentions the first step necessary to remedy the evil—to get rid of the unwholesome tenements. He does not think it necessary to have such places for such people; no improvement need be looked for while the houses are allowed to remain as they are. In the main, it is not want of money that keeps people in such houses; they pay in small sums what amounts in a year to an extravagant rent for such accommodation. Dr. Russell closes by commending the work of Miss Octavia Hill, who seems to have solved, in London, some of the problems connected with the housing of the poor; and by advocating the adoption in Glasgow of certain recommendations carried out in Edinburgh with reference to St. Giles's Ward there.—The subject of the better housing of the poor was under consideration again last week in the Philosophical Society, when an excellent paper was read by Mr. William Smart, M.A. He described the state of matters in Glasgow, fully enough detailed above, and concluded by giving an account of various philanthropic companies which are now providing in London habitable houses on remunerative commercial principles.—The question of the "housing of the poor" has been taken up also by the Church of Scotland. The first public meeting of the Commission appointed by the Presbytery of Glasgow was held a few days ago, when Dr. J. B. Russell was the only witness examined. He showed the relation which exists between house accommodation and death-rate in the eight principal towns in Scotland. It may be mentioned that the scope of this Commission is to inquire into the housing, the social surroundings, and the moral condition of the poor, and to suggest remedial measures if these seem urgently required. The term "poor" is used to designate those whose wages run from 3*s.* to 20*s.* per week.

Glasgow, Dec. 17th.

ABERDEEN.

The Medico-Chirurgical Society.

One hundred years ago, on Dec. 14th, 1789, the first meeting of the Aberdeen Medico-Chirurgical Society was held; and on Saturday, the 14th inst., the present members celebrated the centenary by holding a dinner in their hall, 29, King-street. Dr. Smith-Shand, the President, was in the chair, and the croupiers were Dr. Garden, the Vice-president, and Dr. Edmond, the Secretary of the Society. Among the guests were Dr. Tyler, the Gifford Lecturer; Dr. Macalister, the Thomson Lecturer; Principal Geddes; Lord-Provost Stewart; and Mr. Peter Esslemont, M.P. Fifty years ago the jubilee of the Society was celebrated, and of the members then present three are still living—viz., Mr. Jamieson of the Aberdeen Lunatic Asylum, Dr. James Will, and Dr. Francis Edmond, the Society's legal adviser. After the loyal toasts, the President proposed "The Aberdeen Medico-Chirurgical Society," and in his speech gave an interesting account of the history and progress of the Society. The first secretary, he said, was a certain James McGrigor, who hailed from Strathspey. He afterwards became Sir James McGrigor, and was ultimately appointed Director-General of the Army Medical Department. The first treasurer was a George Kerr, who afterwards was a medical practitioner in the city. The portraits of these gentlemen hang on the walls of the hall where the Society dined. The Society at present consists of fifty-one members; its funds are divided into the ordinary fund, the buildings fund, the library fund, and the widows' fund; and they all show balances on the right side. To the widows' fund the late Dr. Robert Beveridge left a handsome legacy; and by another legacy the Society has at its disposal a medical bursary of £20. Mr. Jamieson (Peterhead) proposed "The President of the Medico-Chirurgical Society." Dr. Garden proposed "The Founders of our Society," and in doing so gave several interesting and amusing extracts from the old minute book of the Society. At first the Society was composed entirely of medical students. They met once a week, at first at their own residences, but this being found inconvenient, a class-room in Marischal College was placed at their disposal. Each meeting had its own president, and each member was obliged to take the presidentship in turn. Regular attendance at the meetings was enforced by fines.

Digitized by Google

A record was kept of the subjects discussed or, "as it is quaintly phrased in the minute book, 'agitated.'" The following are some of them: "How far is a knowledge of Mathematics consistent with, and useful to, Medicine?" "Is an accurate knowledge of Anatomy absolutely necessary to Medicine?" "Are Hysteria and Hypochondriasis the same thing?" Convulsions or inward fits were thought to be due to redundant bile and superabundance of acidity in the stomach. The Society, composed as it was at that time of students, seems to have been the working part of the Medical School, and we find that the members met for "Lessons in Anatomy," when one of their number had to give his fellows an anatomical demonstration. Dr. Garden said they evidently believed in the maxim that "all work and no play makes Jack a dull boy," for the minute of one meeting at which office-bearers had been appointed ends thus: "We then proceeded to the tavern, where we spent the greater part of the meeting in mirth and jollity." In little more than a year after the formation of the Society qualified medical practitioners were admitted as extraordinary members, and from that date up to 1863 there were junior members or students, and senior members or practitioners. Since 1863, however, there had been no student members. Dr. Macalister proposed "The University of Aberdeen," which was responded to by Principal Geddes. On rising to reply to the toast of "The Aberdeen Medical School," proposed by Sheriff Dove Wilson, Dr. Struthers received quite an ovation. Other toasts followed, and in every respect the centenary dinner was a great success, and evidently enjoyed by everyone.

Aberdeen, Dec. 18th.

DUBLIN.

(FROM OUR OWN CORRESPONDENT.)

Royal College of Surgeons in Ireland.

AT a meeting of the Council held last week, the honorary Fellowship of the College was unanimously conferred upon Mr. Thomas Heazle Parke, A.M.D., a Licentiate of the College, in recognition of his distinguished services in the expedition of Stanley across Africa. At the same meeting, the President, Mr. Meldon, was congratulated by the Council on having been appointed a deputy lieutenant for the city of Dublin.

Accident to Sir Charles Cameron, M.D.

I regret to state that an unfortunate accident on Friday last has incapacitated the genial and well-known medical officer of health for Dublin. It appears that shortly after leaving his house on Friday evening he tripped over a heap of stones and fell, breaking three of his ribs on the left side.

The late Mr. Jameson Dwyer.

The following resolution was unanimously adopted at a recent meeting of the Cork Town Council: "That we, the Corporation of Cork, tender to the family of Dr. Dwyer, late resident medical superintendent of the Cork District Lunatic Asylum, our sincere sympathy on his demise, and express our great regret at the loss they have sustained by the death of such an amiable gentleman and fond father."

City of Dublin Hospital.

Dr. W. J. Smyly, having been appointed Master of the Rotunda Lying-in Hospital, has resigned his position on the staff as gynæcologist to this institution. The governors have passed a resolution expressing their sense of the value of his services and their appreciation of his skill and attention whilst holding the office of gynæcologist.

The Lord-Lieutenant has appointed Dr. Oscar Woods, resident medical superintendent of Killarney Lunatic Asylum, to be resident medical superintendent of the Cork District Lunatic Asylum, in the vacancy caused by the death of Mr. Dwyer. The Cork Asylum is one of the best-paid asylums in Ireland, and the post was the object of much competition. Mr. L. T. Griffin, visiting physician to the Killarney Asylum, succeeds Dr. Woods as resident medical superintendent.

The Public Health Committee of the Corporation of Cork have strongly recommended the adoption of the provisions of the Infectious Diseases Notification Act for that city.

The bazaar lately held in the Town Hall, Kingstown, for the Monkstown Hospital, has realised a sum of £464. This amount will be placed to the credit of the building fund.

Dublin, Dec. 17th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Prophylaxis of Tuberculosis.

WITH reference to the report of Professor Villemin on the prophylaxis of tuberculosis, Professor Hardy, who opened the discussion at a recent meeting of the Academy of Medicine, summed up his opinion as follows: As regards the measures by the aid of which one might hope to restrain the development of phthisis, the first place belongs to general hygiene, which aims at fortifying the offspring of those affected with tuberculosis and other debilitated subjects. M. Hardy protested against the publication of details relative to the contagion of tuberculosis, and in the name of humanity he would not have tuberculous subjects looked upon as pariahs or outcasts who should not be approached. If the counsels of certain ultra-contagionists be followed, it would be feared that the patients would be abandoned, or at least that they would not receive the physical and moral care which they require. It is particularly on account of these latter considerations that M. Hardy refused his vote in favour of the propositions of the Commission, but only as far as concerns their being addressed to the public. M. Trasbot, professor of clinical medicine at the veterinary school at Alfort, declared that he could only consider one side of the question. He stated that the bovine origin of tuberculosis is not proved in an irrefutable manner, and, in any case, it is far from being so frequent as is generally supposed. There does not exist any example of the experimental transmission of tuberculosis from the ox to man. Even clinically this has not been demonstrated, although it is affirmed without reserve that bovine tuberculosis is transmitted to man by meat, blood, and milk, and this on the grounds of experiments performed with divers animals. If, moreover, this transmission is effected, it is infinitely less frequent than is thought, and can have no share whatever in the incessant augmentation of the malady in man. That which proves this last proposition is that whereas tuberculosis is becoming more and more common in the human species, it is being diminished amongst cattle in considerable proportions. In 1888, according to the report of M. Alexandre, Chief of the Sanitary Service of the Seine, of 24,724 animals from different parts, which appeared in bad condition, 125 only were found, at the necropsy, to be tuberculous. This is a very small proportion relatively to the number of animals annually killed in Paris. It is therefore impossible to attribute the numerous cases of human tuberculosis to infection produced by meat. The hypothesis of contamination by blood is not worthy of discussion. As regards that by milk, it must be very limited, if it does exist, as tuberculosis is becoming excessively rare in the milch cows kept in Paris and its environs. In presence of the possible danger resulting from the consumption of tuberculous meat, the authorities have prohibited the sale of such meat; this of course is a rational measure. The Congress on tuberculosis, by exaggerating the fear of contagion by tuberculous meat and milk, has spread a kind of panic among the public. To a remark made by M. Necard, M. Trasbot observed that he never had the idea of disputing the identity of bovine and human tuberculosis, but that there was no certainty of the transmission of tuberculosis from the ox to man through the ingestion of the flesh of this animal. Professor Cornil, who is a confirmed contagionist, approves the instructions of the Congress, which, he thought, should be widely published. According to this authority, there is no doubt of the contagiousness of this malady, and in support of his thesis he cited that the Fuegians did not know what phthisis was before the installation of the English mission. The wife of the pastor, who was phthisical, had collected in a school a certain number of children. These young Fuegians were lodged, clothed, and placed under apparently better hygienic conditions than those who still lived in a savage state. Notwithstanding this, a terrible mortality occurred among the former. There was a veritable epidemic of acute phthisis.

Lunatics at Liberty.

In resuming his clinical lectures at the Sainte Anne Asylum, Professor Ball delivered a very interesting lecture on Lunatics at Liberty, a subject he had selected *à propos* of the following remarkable case. A very intelligent man,

Digitized by Google

occupying a respectable position in the world, married rather late in life, and without knowing the antecedents of his intended wife, whose father had for a long time been insane. This woman was before long seized with the delusion that she was the object of the animosity of her neighbours. The husband at first endeavoured to show his wife her error, but he ended by finding himself drawn into the same delusion. This, the learned Professor observed, was one of those curious cases of dual insanity, or *folie à deux*, which are far from being rare. This man one day went into the street with a revolver in his hand, and, imagining that his honour was impeached, he sought in vain the other lodgers in the house, who, as he supposed, wished to seek a quarrel with him. Of course nobody regarded his challenge. One day he heard a voice provoking him to a duel, and, satisfied that he had found an antagonist, he went at four o'clock in the morning to the place appointed for the combat, outside the fortifications, but found no adversary. Disappointed, he went to the Commissary of Police of his quarter to lodge a complaint. The Commissary advised him in a friendly manner to go and see the Procureur of the Republic, to whom he was conducted. This judicial functionary happened to be a physician, by whom the patient was sent to the Sainte Anne Asylum, where he has been for four years. The man is still in the asylum, but he is stated to be perfectly cured.

La Grippe.

The epidemic of influenza, or *la grippe*, which has been raging in Paris for the last fortnight, is on the decline. No deaths from the disease have been recorded.

Paris, Dec. 17th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Richard von Volkmann.

BEFORE beginning his lecture in the Surgical Hospital here on the day after Volkmann's death, Professor von Bergmann addressed his hearers as follows: "About twenty-five years have elapsed since Volkmann began his academic career. He was one of the first surgeons who "domesticated" Lister's antiseptic method in Germany, and the brilliant successes which he gained by it went far to confirm it and to gain its acceptance. Another part of his work was the study of cancerous tumours, and it occupied him till the last days of his life. His great excellence as a clinical teacher and as a military surgeon during the last campaigns is sufficiently known. But it is not only in his capacity as a scientist and an operator, but also as a man, that we owe him our admiration, for he was in every respect so true a character, so sincere a man, ever mindful of his great and serious duties. He was a poet too, and a fresh breeze blows through his 'Songs from the Vale of the Sarle'; but especially his widely known and popular 'Reveries at French Firesides' are a proof of his poetic endowment, and a memorial of that time of the great war of 1870-71 which was so glorious for Germany. In him a man has departed who succeeded in gaining a name such as few possess, and who in full measure deserves that his memory be warmly cherished by men of science and by the nation." Dr. von Coler, Physician-General to the Prussian Army, has published the following tribute to Volkmann's memory: "Professor Richard von Volkmann, Surgeon-General *à la suite* of the ambulance corps, head of the surgical hospital of the University of Halle, Privy Councillor in Medical Affairs, and knight of high orders, died on the 28th inst. at Jena. The officers of the Ambulance Corps deeply and sorrowfully mourn the departure of one of its most eminent members, a master of German surgery and of the treatment of the sick and wounded in war. As in the campaigns of 1866 and 1870–71, inspired by high patriotism and genuinely philanthropic feeling, friendly to all good and noble things, he devoted his great knowledge and skill to the service of the army, and was a helper and life-saver to thousands. He remained also after the wars as the honoured deliverer of advanced courses of lectures for military surgeons, and as an active adviser, and an indefatigable promoter of the interests of the medical and surgical department of the army. The gratitude we owe the deceased lives on with his memory, which will for long be kept fresh by the rich fruits of his blessed work." On his death-bed Volkmann contributed 150 marks to the fund for the erection of a monument of the Emperor Frederick on the battle-field of Wörth. In the letter which accompanied the gift he wrote with a trembling hand: "I think, too, that the only suitable place for the chief national monument of the Emperor Frederick is Wörth." He added that, if his health permitted, he would do all that in him lay for the realisation of the scheme. The streets through which his funeral passed in Halle were crowded with spectators.

Leprosy.

Government Counsellor Dr. Wernich draws attention to the circumstance that cases of leprosy have recently been observed very frequently in France and Russia. Considering the large traffic between Germany and those countries, this fact is of serious importance to the Germans, for there is no longer any doubt that leprosy is contagious. This fact was rendered probable by Hansen's discovery that leprosy is caused by a bacillus nearly related to the tubercle bacillus, and further by an experiment which Dr. Arning of Hamburg, who studied leprosy in the Sandwich Islands, carried out there. He wished to find out whether leprosy could be produced in a human being by inoculation. Experiments on animals had either failed or yielded ambiguous results. Dr. Arning, supported by the authorities, induced a criminal condemned to death to let himself be inoculated with leprous tissue, and the symptoms of leprosy became distinctly visible in him within a few months. The results of recent investigations are directly opposed to the opinions which formerly prevailed as to the manner in which leprosy spreads. Heredity used to be regarded as the main factor. Statistical inquiries, however, have shown that this is not the case. In Europe leprosy is still endemic in Finland, the Baltic provinces of Russia, some parts of Sweden, and especially in Norway, and those who wished to study it used to go thither. Now, however, the disease can be very conveniently studied in Paris and St. Petersburg.

The Influenza Epidemic in Germany.

Yesterday's telegrams from various German districts give some idea of the dimensions which the influenza epidemic has attained. In Dantzic so many teachers and schoolboys are ill that only some of the usual lessons are being given in the High School, and several other schools are closed altogether. Work is partially paralysed, too, in the offices, especially in printing offices. In Hamburg several schools have had to be closed. At Wandsbeck, near Hamburg, 3000 cases are announced, and three elementary schools are closed. Professor Leyden, of the Charité, spoke to his students on this subject the other day. He emphasised that influenza is a disease of specific character, by no means deserving the disregard with which it is frequently treated. It must not be placed in the same category as common colds. Its special character was indicated by the suddenness and severity of all its symptoms, especially fever, and above all by its pandemic character. He declared that more than a third of the population were ill at present. He also pointed out that this complaint was very often accompanied by deep mental depression, the patient feeling intensely ill all over in a much higher degree than was usual in common colds. For this reason the treatment of the mind and feelings of the patient deserved the special attention of the physician. He discussed the points of resemblance between influenza and the dengue fever, which has been raging of late in Constantinople, Smyrna, and other Turkish cities, and favoured the theory that the former has sprung from the latter, which generally spread from east to west and from south to north. The *Berliner Klinische Wochenschrift* (Berlin Clinical Weekly) writes: "It can no longer be denied that Berlin too has been attacked by the epidemic, though it is difficult to ascertain how widely it has spread, for most of the cases which go by the name of influenza among the laity are really merely imaginary. Anyone who should reckon every slight attack of bronchial catarrh with fever, such as the season brings with it, all colds in the head and headaches, under this rubric, would have to state a very high percentage of cases in Berlin too. Whoever, on the other hand, demands a stricter diagnosis, especially whoever requires a distinct appearance of the nervous symptoms, along with the varying and complex objective symptoms, with the partly catarrhal, partly gastric, disturbances, will be more cautious with his statistics. All trustworthy observers lay special stress on the fact that there is a striking and charac-

Digitized by Google

teristic disproportion between the objective symptoms, including even the often high but very transient fever, and the subjective feeling of illness, the weariness and depression. Real cases, however, have also been observed—in the Charité for instance—with absolute certainty, and it has been pointed out that the complaints which are notoriously wont to accompany influenzâ epidemics—viz., catarrhal and croupous pneumonias—have unmistakably increased. In these cases antipyrin or antifebrin seem to have been universally prescribed, with the effect that the subjective state very rapidly improved." A committee of eminent men, including several of the most highly reputed physicians, has been formed for the purpose of tabulating statistics of the epidemic in Berlin, and the assistance of the Statistics Office of the city has been secured.

Professor Rudolf Virchow.

On the 11th inst., the Berlin Anthropological Society presented its President, Professor Rudolf Virchow, with a bronze medallion portrait of himself by Anton Scharff, in remembrance of the foundation of the Society twenty years ago. It held its first public sitting on Dec. 11th, 1869, with Virchow in the chair, and he has been the soul of it ever since.

Berlin, Dec. 17th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Influenza Epidemic.

THE number of cases of influenza rapidly increased last week. Most of the lectures and courses at the hospital had to be suspended on account of the illness of the respective lecturers. The hospital wards, which are filled with patients every year at this season, are now so overcrowded that many patients have to lie on the floor, and numbers of people applying for admission have to be refused. Besides the civil, the military portion of the population is also suffering greatly from the disease, and in some regiments here 30 per cent. had to be sent to the military hospitals from that cause. There are, in addition, many thousands of the population under private treatment; but, as there is no compulsory notification, the number cannot be stated even approximately. The weather has been somewhat foggy during the last few days, with a rising temperature. The cases which came under observation were altogether of a mild character, the fever lasting only from twenty-four to thirty-six hours, and the patients recovering after two days. Complications were rare, only two cases of catarrhal pneumonia having been observed as a result of influenza up to the present at the General Hospital; but several cases of relapse in patients who had already recovered from the first attack have been reported to me. Accounts of the outbreak of the disease in several provincial towns of Austria have also been received here. The majority of the physicians in Vienna consider the disease to be non-contagious, and in the course of a lecture delivered last week Professor Nothnagel called attention to the miasmatic character of the disease, which does not spread along the usual lines of traffic.

Demonstrations against a Professor.

At the Gratz University the Professor of Anatomy, Dr. Holl, had, by a recent order of the Minister of Public Instruction, to suspend his examinations on account of demonstrations made by the students.

Vienna, Dec. 16th.

ROYAL COLLEGE OF PHYSICIANS.

A COMITIA of the College of Physicians was held on the 19th inst., Sir Andrew Clark, Bart., President, in the chair. The gift of a portrait of Dr. Chowne, a late Fellow of the College, was announced by the treasurer.

The President stated that he had appointed Dr. Andrew to be the Harveian Orator for 1890, and Dr. Saundby to be Bradshaw Lecturer.

The names of the gentlemen who had recently passed the examination for the diploma of Public Health were submitted, and the diplomas directed to be issued.

Reports upon the subject of Leprosy, furnished by the Colonial Office, from Cyprus and the Cape of Good Hope, were received. Each report expressed belief in the communicability of the disease and the need for measures of isolation. These reports were referred to the Standing Committee on Leprosy.

A communication from the University of London, enclosing a draft scheme of the Senate for reconstituting the University, was next considered, and, after some discussion, was referred to the committee which had been appointed to report on this question.

A communication from the Royal College of Surgeons notifying the appointment of Messrs. Marshall, Hulke, and Bowlby upon the Laboratories Committee, was read; also communications from the Metropolitan Asylums Board respecting the ambulances of the Board, and the question of clinical work in the fever hospitals.

In response to an invitation from the Pharmacopœia Committee of the General Medical Council, the following Fellows were nominated to form a committee to suggest any new remedies it might be desirable to add to the Pharmacopœia:—Sir A. Garrod, Drs. Broadbent, Ord, C. T. Williams, J. M. Bruce, B. Yeo, F. Taylor, Biss, Lees, Murrell, F. T. Roberts, Stone, Warner, and L. Brunton.

The subject of the Regulations for the Diploma of Public Health was referred to the Council to discuss and report to the Committee of Management, with the object of bringing these regulations into harmony with the requirements of the General Medical Council.

On the recommendation of the Council, it was resolved, for the first time, to abrogate the Bye-law (xliii.) relating to vice-presidents, and it was referred to the Council to consider how the duties of vice-president might in future be carried out.

It was also resolved, on the recommendation of the Council, "That the substance of the official communication from the Government, in reference to the terms on which in future English medical men will be allowed to practise in France, be communicated to the medical journals and to the chief daily papers, with the intimation that the Royal College of Physicians has been requested by the Government to make the matter known to the profession in England. And that a subcommittee, composed of the Senior Censor (Dr. Bristowe), Sir William Roberts, M.D., Dr. Pavy, Dr. Pye-Smith, and the Registrar, be appointed to consider the communication from the Foreign Office, and to report thereupon to a future meeting of the Council."

Respecting the extension of the curriculum, the following resolution was passed and directed to be transmitted to the General Medical Council: "That while admitting that the extension of the medical curriculum to five years would conduce to the better education of medical students, and is desirable, they are not prepared at present to make any recommendation on the subject."

It was also resolved to rescind the resolution of the College transferring the nomination of Examiners on the subject of Hygiene to the Committee of Management, and that two Examiners be nominated, as in other subjects, by the Council.

Reports from the Committees upon the Fittings for the new Laboratories, and the Regulations respecting them, were received and adopted; and on the nomination of the President, the following three Fellows were elected as representatives of the College on the Laboratories Committee—Sir W. Roberts, Dr. Pye-Smith, and Dr. Payne. These gentlemen, together with the three nominated by the Royal College of Surgeons (*vide supra*), are empowered to appoint the Director of the Laboratories.

Medical News.

UNIVERSITY OF LONDON: M.D. EXAMINATION.—The following is a list of candidates who have passed the respective examinations mentioned below:—

Medicine.—John Hill Abram, University College, Liverpool; Evelyn Oliver Ashe, London Hospital; Percy Ashworth, B.S., B.Sc., Owens College and Manchester Royal Infirmary; James Thomas Bays, St. Mary's Hospital; Robt. Bird, B.S., St. Bartholomew's Hospital; J. R. Bradford, D.Sc. (Gold Medal), and Weldon Cragg Carter, University College; Wayland Charles Chaffey, St. Bartholomew's Hospital; Wm. Fredk. Clarke, B.S., and Herbert Evelyn Crook, B.S., Guy's Hospital; Hilarn. M. Fernando, B.Sc., and John Lacy Firth, University College; Theodore Fisher, Guy's Hospital; Leonard

Digitized by Google

Maurice Gabriel, St. Bartholomew's Hospital; John Edwin Gould, University College; George William Hill, B.Sc., and Arthur Pearson Luff, B.S., St. Mary's Hospital; H. Grabham Lys, London Hospital; Henry John Macevoy, B.Sc., St. Thomas's Hospital; Alfred Alex. Mumford, Manchester Medical School and Royal Infirmary; C. Drummond Muspratt, B.S., Guy's and Sussex County Hospitals; *John Porter Parkinson and Wm. Bramwell Ransom, B.Sc., University College; William Newt Risdon, B.S., Guy's Hospital; Harry Arthur Sansom, St. Thomas's Hospital; Hugh Smith, London Hospital; *Edgar Herbert Thane and Edward Francis Willoughby, University College; William George Willoughby, St. Bartholomew's Hospital.

State Medicine.—Charles Edwd. Baddeley, King's College; F. François Burghard, M.S., Guy's Hospital; William Barltrop Featherstone, Birmingham School.

M.S. Examination.—Henry Percy Dean, B.Sc., University College; Alfred Parkin, Guy's Hospital.

B.S. Examination.—First Division: Alfred George Francis, St. Bartholomew's Hospital; Charles Arthur Kent, B.Sc., University College; Charles MacGowan Kitching and Robert Devereux Mothersole, Guy's Hospital; Berkeley Geo. A. Moynihan, Yorkshire College; Gilbert Benjn. Mower White, University College.—*Second Division:* George Black, Guy's Hospital; Wm. Soltau Fenwick, London Hospital and Strasburg and Berlin; Alfred Downing Fripp, Guy's Hospital; Francis Horatio Napier, St. Bartholomew's Hospital.

* Obtained the number of marks qualifying for the Gold Medal.

COLLEGE OF PHYSICIANS IN IRELAND.—The following gentleman has been admitted a Member of the College:

Albert Croly.

The diploma in Sanitary Science has been obtained by

James H. Poland.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—FELLOWSHIP EXAMINATIONS.—The following gentlemen, having passed the necessary examination, were admitted Fellows of the College:—

Louis Aloysius Byrne, L.R.C.S.I. 1885, L.K.Q.C.P.I. 1886, and Edmund Rundle, L.R.C.S.I. 1878, L.K.Q.C.P.I.

NEW MUZZLING ORDER.—A new muzzling order is published in a supplement to the *London Gazette* of Wednesday, extending the regulations at present in force, and making them applicable to various boroughs and counties throughout England, which is to take effect from and after Dec. 31st until further notice.

RABIES.—The number of dogs in England officially reported during the week ending Dec. 7th as affected with rabies was six against three in the previous week. All were killed. The distribution was as follows:—Kent, Middlesex, and Surrey (all exclusive of London) one each; York (West Riding) three.

SOCIETY FOR THE STUDY OF INEBRIETY.—A quarterly meeting will be held on Jan. 7th, 1890, in the rooms of the Medical Society of London, Chandos-street, Cavendish-square, at 4 o'clock, the President, Dr. Norman Kerr, in the chair. Paper: "The Law relating to Drunkenness and Inebriety," by J. R. McIlraith, Esq., M.A., LL.B., of the Middle Temple, barrister-at-law, Associate.

INFECTIOUS HOSPITAL, SURREY.—Last week, the deputations from the Sutton and Carshalton Local Boards met the members of the Epsom Board in committee to consider the advisability of erecting a joint fever hospital for the parishes of Epsom, Carshalton, and Sutton. It was unanimously decided that such a hospital was desirable for the combined districts. The plans &c. are to be the subject of further discussion.

THE COUNTESS OF DUFFERIN'S FUND.—The first annual report of the United Kingdom Branch of the National Association for Supplying Female Medical Aid to the Women of India is of an encouraging character. Since the fund opened in England in March last £1239 9*s.* has been received in subscriptions and donations; of this amount £310 19*s.* 5*d.* has been expended, leaving a balance on Nov. 30th of £1481 10*s.* 6*d.* When in full operation it is estimated that the United Kingdom Branch will require at least £1000 annually, and this sum the committee would like to make up by a thousand annual subscriptions of £1 each from as many ladies in Great Britain and Ireland. A good many requests have from time to time been received for information regarding the position and prospects in India of lady doctors, midwives, and nurses; these have been promptly complied with, and the applications for employment have been registered to meet the demands of the central committee; but it is not expected that any but fully qualified lady doctors will be required from home, the Indian Schools of Medicine being able to supply the nurses, compounders and dressers, &c.

THE NOTIFICATION ACT.—At the usual meeting of the Metropolitan Asylums Board on Saturday last the chairman stated that under the new Act the notification of all infectious diseases fortnightly in the metropolis during the last two months had been successively 925, 756, 657, 638, and 632.

THE INFLUENZA EPIDEMIC IN DUNDEE.—The steamer *Moravia*, at Dundee from Riga, had three of her crew suffering from the influenza epidemic, contracted by them while at Riga. Almost all the crew were ailing during the voyage, some getting better in a couple of days, whilst others suffered for ten days. They first chilled, then fever supervened, followed by an irritating cough, and then the malady subsided. Every precaution was taken to prevent the contagion spreading from the vessel.

DUNDEE FEVER HOSPITAL.—This new hospital, for the treatment of fever and other infectious diseases, erected by the Police Commissioners at King's Cross, in the northern suburbs of the city, was formally opened by Provost Hunter on the 11th inst. At present only one administrative block and two pavilion wards, each of which contains eighteen beds, have been erected, but the completed plan will comprise five additional pavilions. The present outlay amounts to between £15,000 and £16,000.

GREAT NORTHERN CENTRAL HOSPITAL.—A Loan Exhibition of pictures and other works of art in aid of the building fund of the Great Northern Central Hospital is to be opened by the Marchioness of Lorne, on Monday, Jan. 6th, 1890, in the gallery of the Camden School of Art, 4, St. Bartholomew-road, Camden-road, N. The exhibition will consist of a large number of interesting and valuable works by some of our most distinguished artists and sculptors, and will remain open for ten days.

THE AYR COUNTY HOSPITAL.—At the annual meeting of the supporters of this hospital, on the 9th inst., the report, which was adopted, showed that the total income for the year had been £1528, and the expenditure £1773, showing an excess of expenditure over income of £245. The total amount of debt still on the institution was £2900. The chairman intimated that the Marquis of Bute, the Earl of Stair, and thirteen other gentlemen, had agreed to each subscribe £100 towards clearing off the debt of the hospital—total, £1500.

A MORTUARY FOR GODALMING.—At a recent inquest held at the Charterhouse Arms, the jury, on viewing the corpse, which was lying in a stable of the inn, were greatly shocked at the wet condition of the body through the dilapidated state of the building. Subsequently the coroner expressed the necessity of providing a mortuary for the district of Godalming, urging the jury to take the necessary steps for that purpose with the proper authority. This has been done, and the question will be brought before the Burial Board at the next meeting.

VICTORIA UNIVERSITY.—The following appointments to vacant examinerships were made by the Council at a meeting held on Dec. 12th:—External Examiner in Medicine: Sir Dyce Duckworth, M.D., F.R.C.P. Edin., Lecturer on Clinical Medicine, St. Bartholomew's Hospital, London. External Examiner in Materia Medica and Pharmacy: J. Mitchell Bruce, M.D., F.R.C.P., Lecturer on Therapeutics, Charing-cros Hospital, London. External Examiner in Botany: G. R. M. Murray, F.L.S., senior assistant, Department of Botany, British Museum.

THE POLLUTION OF YORKSHIRE RIVERS.—At an important meeting of the Conservators of Yorkshire Fisheries, held at York last week, a report was presented by the committee appointed to consider the York sewage scheme, and a letter was read from the Local Government Board stating that they were not satisfied that the effluent resulting from the proposed chemical treatment would be properly purified unless it were passed over and through land, and that they would not be prepared to sanction the proposed sewage scheme unless it included satisfactory provision for that purpose. A letter was read from the Ilkley Angling Club, complaining of the pollution of the River Wharfe and the destruction of fish. The pollution of the Swale, at Ripon, the Skell, and the Aire was referred to, and a committee was appointed to communicate with the County Councils with reference to the pollution of the rivers of Yorkshire. The meeting con-

Digitized by Google

sidered other questions of public interest, including the Wharfe navigation improvement scheme, the protection of grayling, and the illicit traffic in salmon.

SAVAGE ATTACK ON A PRISON DOCTOR.—At Usk Prison recently, while Mr. D. F. Boulton, the medical officer, was going his round, he was attacked by a prisoner named Williams. The door of the prisoner's cell was opened by an attendant warder for the doctor to enter, and the latter was immediately afterwards felled by Williams, who struck Mr. Boulton on the head with a heavy roller. The doctor fell insensible, but the warder prevented any further injury. Williams was immediately taken before the visiting justices, and was sentenced to thirty-six strokes with the cat.

INCREASED ACCOMMODATION FOR LUNATICS IN SOMERSET.—On the 5th inst. a conference of the Asylum Committee of the Somerset County Council and the representatives of Boards of Guardians of the county was held at the Town Hall, Highbridge, to consider the question of accommodation for lunatics, idiots, and imbeciles. The meeting was arranged consequent upon a report from the committee that there were few vacant beds in the institution at Wells. After a prolonged discussion it was resolved that a second asylum be built in the western part of the county.

VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION. The official inspection and examination took place this week at the headquarters of the London Scottish R.V. The examiners were Surgeons Barnes and Gubbin, Medical Staff. Forty-four men were sent up and all passed. After being taken through a course of stretcher drill, each man had a searching *vivâ-voce* examination. At the conclusion Surgeon Barnes congratulated Surgeon Pearce on the result, and told the men that the class was by far the best he had ever inspected. The next class will be held at the Artists' headquarters, commencing Thursday, Feb. 6th, 1890.

HOSPITAL SUNDAY IN MELBOURNE: A GOOD EXAMPLE.—Oct. 27th was Hospital Sunday in Melbourne. The church that occupies the pride of place in the list is St. John's Church of England, in Toorak, a fashionable suburb. St. John's is credited with a total collection of £1017 12*s.* 6*d.*, but half of this goodly sum is the gift of a wealthy parishioner, the Hon. M. H. Davies, Speaker of the Legislative Assembly. Mr. Davies regularly places a cheque for £500 in the plate every Hospital Sunday. Not long ago he distributed £10,000 amongst the Melbourne charities.

SUICIDE OF A LONDON PRACTITIONER. — Mr. Edward Sandwell, L.R.C.P. Edin., M.R.C.S. Eng., of 10, Soho-street, Soho-square, aged fifty-one, made an attempt to commit suicide on the 12th inst. by inflicting severe wounds with a knife in his throat, and was conveyed to the Middlesex Hospital, where death supervened on Saturday last. The evidence at the inquest was to the effect that the deceased had been very depressed since August last. His memory was impaired, and he was feeble and childish, but attended patients until the day previously to the attempt. His mind lately was somewhat deranged, and steps had been taken to place him under restraint.

ST. ANDREW'S AMBULANCE ASSOCIATION, CRIEFF.—On Saturday, the 14th, Dr. Thom's second course of lectures was brought to a conclusion, when Dr. John Dunlop of Glasgow examined the pupils, both ladies and gentlemen, for certificates and medallions. There were fifty-two on the roll, and of these thirty-eight presented themselves for examination. The examination was, as usual, largely practical, and at the close Dr. Dunlop said that, though he was not permitted to state anything definitely as to the result, since his report had first to go to headquarters, he would simply remark that he was well satisfied, and that Dr. Thom had evidently spared no pains to bring them to a high state of efficiency. He inculcated prudence and modesty in the application of their knowledge. Dr. Thom's first course of lectures was delivered nearly four years ago, when there were over a hundred on the roll, and nearly seventy passed the examination. Besides these lectures, Dr. Thom has during the last five years conducted two courses of instruction for Volunteers, of whom over twenty have passed the War Office examination, wear the Geneva Cross, and constitute the stretcher-bearers of the 4th Volunteer Battalion of the Royal Highlanders (Black Watch), in which corps Dr. Thom holds the rank of surgeon.

METROPOLITAN AND PROVINCIAL HOSPITAL SUNDAY COLLECTIONS.—The committee of the Pimlico United Temperance, Friendly, and other Societies' Sunday demonstration, which took place a short time since in aid of the funds of the Belgrave Hospital for Sick Children, last week handed over to the Hospital authorities £130 17*s.*—The net result of the current year's Hospital Sunday collections at Hull amounted to £610, which is to be divided thus: Hull Royal Infirmary, £480; Dispensary, £62; Children's Hospital, £51; and Homœopathic Dispensary, £17.

EMIN PASHA'S CONDITION. — A telegram from Zanzibar dated the 12th inst. gives the following bulletin respecting Emin Pasha's condition received from Bagamoyo: "Emin Pasha suffered severely on the evening of the 9th inst. from a distressing cough and difficulty in expectoration, but was somewhat better yesterday. All signs of blood in the sputa have gone, and the injured eye is almost completely restored. Serum still continues to ooze from the right ear. The patient requires assistance in every movement, owing to the severe contusions, the discoloration of which is, however, gradually going. He is in good spirits. (Signed) PARKE, Surgeon."

BEQUESTS AND DONATIONS TO HOSPITALS.—The Corporation of London has granted 100 guineas to the Royal Maternity Charity, Finsbury-square, and 200 guineas to the Royal General Dispensary, Bartholomew Close.—The late Mr. Charles William Stoughton, of Grosvenor-place, Belgrave-square, London, has bequeathed £300 to the St. George's Hospital, Hyde Park Corner.—Mr. William Westgarth, late of Bolton-gardens, London, has left by his will £500 to the Edinburgh Infirmary.—The City of Dublin Hospital has received £300 under the will of Mrs. McDowell, and a similar amount from the executors of the late Mr. J. R. Berwick.

THE SANITARY DEPOT, HORNSEY.—Mr. R. D. M. Littler, Q.C., chairman of the Middlesex County Council, formally opened on the 13th inst. a new sanitary depôt for Hornsey, erected in the High Street by the Local Board of Health. The prominent features of the depôt are a mortuary with coroner's court and necessary accessories, and a dust destructor for destroying the house and road refuse of the parish. In the first instance the Board erected the mortuary. Subsequently, a steam laundry, disinfector, fumigator, ambulance sheds with stabling, and finally the building for the treatment of house &c. refuse. The cost of the whole works has been about £13,000.

NEUROTIC SCHOOL BOARD CHILDREN.—On Thursday afternoon at the meeting of the School Board for London, Dr. Savage, on behalf of a deputation from the Council of the British Medical Association, presented a memorial pointing out that many children were nervously unfitted for the ordinary course of instruction, but might receive a useful education if it were conducted on special lines. There were children of so peculiar a brain construction that unless the defect were early detected and specially treated, they would develop into criminals and vagabonds. On the motion of Dr. Gladstone, the request for permission to examine all Board school children was referred to the management committee.

THE VICTORIA INFIRMARY OF GLASGOW.—At the second annual meeting of the Court of Contributors held on Thursday, the 5th inst., the governors in their report regretted their inability to announce the completion of the section of the buildings at present in course of construction, and the opening of them for the reception of patients, owing to the strikes and other causes. The completion and opening may, however, be expected some time next month (January, 1890). The principal wards, corridors, and staircases will be lighted by electricity, which, with the heating and ventilating improvements adopted, will conduce to the health and comfort of the patients. Dr. Donald Mackintosh, formerly resident assistant in the Eye Infirmary, and subsequently senior assistant in Belvidere Hospital, has been appointed resident medical superintendent of the Victoria Infirmary out of many applicants for the post. The report acknowledges the great practical ability brought to bear by the governors specially elected by the representatives of workmen contributing to the funds of the institution on many of the matters connected with the erection of the buildings, and which has been of eminent service to the board

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ASHE, E. OLIVER, M.D. Lond., late House Physician, has been appointed House Surgeon to the London Hospital.

BIRKENHEAD, HAROLD, L.R.C.P. Lond., M.R.C.S., has been appointed Junior House Surgeon to the Royal Albert Edward Infirmary and Dispensary, Wigan, vice E. C. Lomas, M.B. Vict., M.R.C.S., promoted to be Senior House Surgeon.

BOSWELL, J. J., M.D. & L.R.C.P. Lond., has been reappointed Medical Officer to the Port and Union District, Faversham.

BROWN, JOHN, M.D. Vict., B.S., D.S.Sci., &c., has been reappointed Medical Officer of Health to the Borough of Bacup, and Physician to the Sourhall Fever Hospital.

BURGHARD, FRÉDÉRIC F., M.D., M.S. Lond., F.R.C.S., late Surgical Registrar to Guy's Hospital, has been appointed Assistant Surgeon to King's College Hospital, vice Mr. Watson Cheyne, F.R.C.S., appointed Surgeon.

BURKITT, J. C. S., M.D., M.Ch. Irel., has been reappointed Medical Officer for the Whitwick Union District.

DAVISON, JAMES, M.D., M.R.C.P., has been appointed Honorary Physician to the National Sanatorium for Consumption and Diseases of the Chest, Bournemouth, vice Dr. Falls, deceased.

DEAN, THOS., M.D. St. And., M.R.C.S., has been reappointed Medical Officer to the Burnley Union and Rural Districts.

DUCKET, C. ALEX., L.R.C.P. Lond., M.R.C.S., has been appointed House Surgeon to the Great Yarmouth Hospital.

FRY, J. FARRANT, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of the Shepton Mallet District Hospital.

HARRISON, A. J., M.B. Lond., M.R.C.S., L.S.A., has been reappointed Physician to the Bristol General Hospital.

HICKS, PHILIP, B.A., M.B. & B.S. Cantab., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the Warneford Hospital, Leamington, vice Bernard Rice, M.D. Lond., resigned.

HINGSTON, ANDREW, M.R.C.S., L.S.A., has been reappointed Medical Officer of Liskeard Union District.

IDESON, J. J., L.S.A., has been reappointed Medical Officer for the Colne District of the Burnley Union.

JOLLY, S. BLAKE, M.B. Cantab., M.R.C.S., L.S.A., has been appointed Medical Officer of Health to the Lewisham District.

LAWSON, SAMUEL, L.F.P.S., L.M. Glas., has been reappointed Medical Officer for the Marsden District of the Burnley Union.

MACLEOD, CHARLES G., M.A., M.B., C.M. Edin., L.R.C.P., has been appointed Junior Assistant Medical Officer to the Saint Andrew's Hospital, Northampton, vice A. L. F. Robertson-Fullerton, M.B., C.M., resigned.

MARSH, N. P., M.B. Lond., M.R.C.S., has been appointed Physician to the Children's Infirmary, Myrtle-street, Liverpool.

PEARSON, A. E., M.R.C.S., L.R.C.P. Edin., has been appointed Resident Medical Officer to the Leeds Borough Hospitals, vice J. Hick, M.R.C.S., L.R.C.P. Edin., resigned.

RHODES, JAMES, M.R.C.S., L.S.A., has been reappointed Medical Officer to the Glossop Union and Rural Districts.

STIRLING, ALEX. WILLIAMSON, M.D. Edin., has been appointed Medical Officer of Health for Grays, Essex, vice S. J. J. Kirby, M.D., resigned.

TEED, F. L., has been appointed Public Analyst for Camberwell.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

BIRMINGHAM AND MIDLAND SKIN AND LOCK HOSPITAL.—A Third Officer on the Acting Medical Staff.

CHELMSFORD UNION, Chelmsford.—Medical Officer, including the office of Public Vaccinator, for the Eighth District of this Union. Salary £140 per annum (which includes all medicines and appliances), together with the extra fees allowed by the Orders of the Local Government Board, and a sum of 12s. 6d. for each Midwifery case. The Vaccination Fees are 2s. 6d. at the surgery or within a mile from the Vaccinator's residence, 3s. up to two miles, and 4s. over that distance.

CHELTENHAM GENERAL HOSPITAL.—House Surgeon. Salary £80 per annum, with board and apartments.

DERBYSHIRE GENERAL INFIRMARY.—Resident Assistant House Surgeon, for six months. No salary, but a bonus of £10 is given.

Births, Marriages, and Deaths.

BIRTHS.

BREACH.—On Dec. 11th, at The Cottage, Yattendon, Berks, the wife of J. H. Breach, M.R.C.S., of a daughter.

COOKE.—On Dec. 9th, at Warrior-square, St. Leonards-on-Sea, the wife of John Cooke, M.B. Lond., of a son.

DAVENPORT.—On Dec. 6th, at St. Kilda, Melbourne, the wife of Dr. Arthur F. Davenport, of a daughter.

DISMORR.—On Dec. 12th, at Tudor Lodge, Lewisham, the wife of Henry Dismorr, M.R.C.S., of a daughter.

HILL.—On Dec. 9th, at Southsea, the wife of Surgeon C. B. Hill, Medical Staff, of a daughter.

PECHELL.—On Dec. 11th, at Curragh Camp, Ireland, the wife of Surgeon A. A. Pechell, M.B., Medical Staff, of a son.

RITCHIE.—On Dec. 4th, at Tranent, N.B., the wife of D. Ritchie, M.D., of a son.

RYLE.—On Dec. 12th, at Northland, Hadley-green, Barnet, the wife of Dr. R. J. Ryle, of a son.

TAYLOR.—On Dec. 16th, at Kennington-park-road, S.E., the wife of Herbert Taylor, M.B., of a son.

MARRIAGES.

BATEMAN—GARROD.—On Dec. 11th, at St. Mary's, Bath, by the Rev. Prebendary Coleman, assisted by the Rev. J. S. Barrett, Frederic John Brownfield Bateman, L.R.C.P., L.R.C.S. Ed., eldest son of Dr. Bateman, F.R.C.P., J.P., of Norwich, and of Burlingham Lodge, Alburgh, Norfolk, to Mary Stuart, daughter of the late C. W. Garrod, Esq., solicitor, Wells, Somerset.

ELKINGTON—OMMANNEY.—On Nov. 20th, at St. John's Church, Peshâwur, Henry Percival George Elkington, Surgeon Medical Staff, to Helen Violet, third daughter of Coll. E. L. Ommanney, C.S.I., B.S.C., Commissioner, Peshâwur.

FROSSARD—MARTIN.—On Dec. 17th, at St. Mark's, Lewisham, Emilien Edward Frossard, M.R.C.S., L.R.C.P., of Bishop's Lydeard, Somersetshire, son of the Rev. Emilien S. Frossard, M.A., late Chaplain of the British Consulate, Bordeaux, to Margaret Rosina, daughter of David Martin, formerly of Croydon, granddaughter of the late Rev. Francis Martin, of London and Bordeaux.

HARDING—ROBERTS.—On Dec. 11th, at Holy Trinity Church, Eastbourne, Charles O'Brien Harding, M.R.C.S., L.R.C.P. Lond., of Highbury, third son of the late J. F. Harding, Esq., of Highbury New Park, to Amy Persis, third daughter of Bransby Roberts, M.D., of Badlesmere, Eastbourne.

LAING—LEITH.—On Dec. 10th, at St. John's Church, Hollington, Alfred William Laing, M.R.C.S., L.R.C.P., of Wellington Lodge, Hastings (late of Summerfield, Putney), to Laura Leighton Leith, youngest daughter of the late R. W. J. Leith, of Castelnau, Barnes, and goddaughter of the late W. Leighton Nutter and Mrs. W. L. Nutter, of Brookwood.

LESLIE—CHANDLER.—On Nov. 7th, at St. Andrew's Church, Calcutta, Surgeon J. T. W. Leslie, M.B., L.M.S., to Eleanor, daughter of the late E. G. Chandler, Esq.

SWEETNAM—HARBORD.—On Dec. 14th, at St. George's, Bloomsbury, J. L. Sweetnam, Staff Surgeon Royal Navy, to Rosalie Harriet, widow of the Rev. C. H. Harbord, R.N., and daughter of the late Major-General R. R. Ricketts, H.M. Indian Army.

WALES—ASTON.—On Dec. 11th, by licence, at Ingoldmells Church, Lincolnshire, A. Wellesley Wales, L.R.C.P.E., L.R.C.S.E., L.A.H.D., Church View, Burringham, Doncaster, late Resident Surgeon, County Antrim Infirmary, Ireland, son of George F. Wales, Esq., M.D., F.R.C.S.E., Landscape, Greenisland, Belfast, to Clara E. Aston, daughter of the late Joseph Aston, Esq., M.R.C.S.E., L.A.C., &c., Barnetby, Ulceby, Lincolnshire.

DEATHS.

HOYLAND.—On Dec. 13th, at Whitworth-road, South Norwood, Charles William Hoyland F.R.C.S., aged 82.

IRVING.—On Dec. 12th, at The Terrace, Tunbridge, Charles Irving, surgeon, aged 44.

TODD.—On Dec. 17th, at 51, Earlham-grove, Forest-gate, John Waterloo Todd, M.R.C.S., L.S.A., formerly of 301, Mile-end-road, E., aged 74.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

POOR PAY FOR APPOINTMENTS TO COLLIERIES, &c.

A Subscriber sends us a form of contract required by a colliery company to be signed by any medical man undertaking to attend their *employés* and their families—say 3600 for £300 a year, or 1*s.* 8*d.* per head per annum, or a farthing and a half per member per week. But even these terms are further complicated and reduced by his undertaking to provide medicines, &c.—which "&c." is a very large order—and by a peculiarly shabby provision that when an additional opinion is required, even in the view of the company, the unfortunate medical man is to provide it at his own expense! Our correspondent thinks we should put our readers on their guard against such engagements, binding for five years on the practitioner, who, on the other hand, may be dismissed by the company at six months' notice. But it would be a poor compliment to our readers to think that they have not sense enough to guard themselves against such illiberal terms.

M.D.—1. The *Medical Record* (New York).—For replies to the other questions we would advise application to Sell's, Fleet-street, London.

Dr. Bell Taylor.—The reports have been received.

THE MASON DEFENCE FUND.

To the Editors of THE LANCET.

SIRS,—The readers of your widely circulated journal are already made acquainted with the trial at law of Mason *v.* Chevens, and it is unnecessary to give further particulars of it, unless to state that it was a professional rather than a personal action, affecting as it mainly does Poor-law medical officers. The Colchester Medical Society, of which Mr. Mason is a member, has already collected at its first meeting the sum of £7 17*s.* 6*d.* towards a fund for defraying the amount of £150, of which Mr. Mason is out of pocket. May I ask you to have the kindness to receive contributions towards this fund? and I shall be happy to act as local treasurer for this district and forward to you a list of such contributions as I may receive.

I am, Sirs, yours faithfully,

GEORGE BROWN, M.D.,
Hon. Sec. to Colchester Medical Society.

Headgate, Colchester, Dec. 18th, 1889.

*** We shall be happy to receive subscriptions on behalf of the Fund.—ED. L.

ENGLISH DOCTORS IN FRANCE.

Fairplay.—A French physician does not require to pass the examination of the English Colleges. He might practise in England without interference.

Mr. Quinby (Liverpool).—The paper will be published in an early number.

"THE COMPARATIVE SAFETY OF ANÆSTHETICS."

Sir Walter Simpson, Bart., writes to us upon the above much-vexed question. He says he is "surprised" how doctors discuss the question, as if it were of any "practical importance." Why our correspondent regards it as trivial is because, "statistically speaking, the percentage of deaths under anæsthetics is so small as to be practically *nil*." He institutes a comparison between deaths due to railway accidents and those arising from anæsthetics; but the parallelism is too strained for persons who, like ourselves, are not mere statisticians to grasp. As far as we are able to understand Sir Walter Simpson, he regards chloroform as a fitting toy for children to play with, and dubs the ordinary precautions taken by skilled chloroformists as superstition. Sir James Y. Simpson, when first experimenting with chloroform, certainly regarded it as a perfectly safe agent; but, unfortunately, the experience which has accrued during the past forty years has shown his belief to have been too sanguine. To a person who looks upon human beings as mere units, useful in making up statistics, a loss of one life in every 2000 or 3000 may seem a bagatelle; but to the medical man, who has to deal with the individual, and, what is more, with the individual's friends, the case is otherwise, and he asks himself, "Could I by any means in my power have saved that life?" If the answer is "Yes," that medical man is—and, we think, rightly—self-condemned, even though the fatality is as a grain of sand in the view of the statistician.

Mr. H. E. H. Matthews.—So far as we can tell, the only apparently suitable place for the case would be one of the undermentioned institutions:—Cripples' Nursery, 15, Park-place, Clarence-gate, Regent's-park; Home for Crippled Children, 17, White Ladies-road, Clifton, Bristol.

W. W.—1. B should be guided by the rule of the place, of which A will inform him. The rule varies in different places.—2. The confusion of names must be met by each practitioner being particular in the description of his own Christian names and professional titles.

C. M. F. and *M.B.* have not enclosed their cards.

HOW DISINFECTION SHOULD BE CARRIED OUT.

To the Editors of THE LANCET.

SIRS,—I shall feel obliged if you will kindly favour me with a reply to the following questions.

In my experience the manner of disinfecting infected premises, as carried out by the sanitary authorities, appears unsatisfactory. The bedding and bed linen are carried from the sick room through the house to their vans, thereby spreading through the house the contagion which up to that time had been confined, as far as possible, to the one room—the room itself being *afterwards* disinfected. In a case of scarlet fever, which only remained in a house a few hours after its development, and in which the attending practitioner fumigated the room for two hours with specially prepared sulphur, the officers of the sanitary authority persisted in carrying out their own process of disinfection. As these matters closely concern medical men in the approaching compulsory notification of infectious disease, I should like to know—(1) Whether their method is a safe one, and if it is the usual one? (2) Whether the authorities have power to enforce their own measures in a case like the one referred to? And (3) Whether a private practitioner would render himself liable by refusing to permit further interference in such cases.

I am sorry to have troubled you with such a matter, but, as I believe it is one upon which we should clearly understand our position, I trust you will favour me. I am, Sirs, yours obediently,

Dec. 11th, 1889. M.R.C.S.

*** 1. We feel convinced that the risk of removing such articles as bedding from an infected room, through the same house as that room is situated in, to a van with a view to disinfection at a properly fitted station, is not to be compared with the much greater risk of professing to disinfect bedding in the infected room. No bedding can be properly disinfected unless it is thoroughly penetrated by a high temperature, unless it is entirely taken to pieces, and each part—as in the case of feathers—exposed to an efficient disinfectant in detail. Hence, attempts to disinfect bedding in private houses must be regarded as most untrustworthy.—2. The sanitary authority has power to enforce "disinfection," and mere exposure of bedding and similar articles to fumes of sulphur or chlorine is certainly not "disinfection" in the proper sense of that term.—3. A private practitioner has no right to interfere with the officers of the sanitary authority in such cases. The owner of the bedding might do so, but, if summoned for obstructing the officers in the performance of their duty, the decision of the magistrates would depend on the evidence submitted to them as to the efficiency or otherwise of the fumigation process; and we doubt whether anyone having skilled knowledge as to disinfecting processes would venture to assert that articles such as bedding, which are so difficult of penetration, could be efficiently disinfected by the exposure of their surfaces to sulphur fumes.—ED. L.

Medical Practice in the Bible.

M. A. asks what prospects for practice a British-educated and registered medical man would have in Jerusalem, and what would be the cost of a Hebrew Bible in the Greek would be most likely to afford him some chance for practice.

C. F. L.—There can be little doubt, we think, of the liability of F. R.—to the Employers' Liability Act, and we recommend him to submit the correspondence to his Solicitor.

A.—The grievance has been repeatedly commented on in THE LANCET. If each person reports to the Registrar-General the number of births he attends, the returns will be complete and perfect.

A. S.—The anæsthetic referred to may be one of the substances sold for the purpose of producing local anæsthesia. The anæsthetics in compliance on the medical man.

Charles pen.—We do not prescribe.

PERIODICAL WORD IN ACUTE RHEUMATISM.

To the Editors of THE LANCET.

SIRS,—Having read with interest, in your issue of Nov. 26th, the case reported by our late fellow-student, Dr. Arthur L. Marshall, of Bristol, I should like to add my testimony to the value of the periodical word in acute rheumatism. I have had a considerable number of cases under my care during the last few years, and have always found that the periodical word has given relief in a very short time. I have also found it of great service in the treatment of sciatica, and in one case of lumbago. The periodical word is, I believe, a combination of salicylic acid and quinine. The case under my care at present is one of acute rheumatism, and I find that the periodical word has given relief in a very short time. I have also found it of great service in the treatment of sciatica, and in one case of lumbago. The periodical word is, I believe, a combination of salicylic acid and quinine. The case under my care at present is one of acute rheumatism, and I find that the periodical word has given relief in a very short time.

I am, Sirs, yours faithfully,

F.R.C.P.

THE RATING OF CHEMISTS' SHOPS.

To the Editors of THE LANCET.

SIRS,—I should be very grateful if [illegible] of your readers who [illegible] of such assessments, in which case I am interested. A certain chemist [illegible] has been assessed at £40, and I am informed that the assessment [illegible] is the highest of any [illegible] in the district. Is this correct? Is [illegible] the highest? Is [illegible] the highest? Is [illegible] the highest?

I am, Sirs, yours faithfully,

Dec. 19th, 1898. F.R.C.P.

THE SANITARY CONDITION OF SCHOOLS.

To the Editors of THE LANCET.

SIRS,—I should be very grateful if [illegible] of your readers who [illegible] of such assessments, in which case I am interested. Remarks

ŒSOPHAGOTOMY FOR THE REMOVAL OF FOREIGN BODIES.

WITH NOTES OF TWO SUCCESSFUL CASES.

By T. A. SOUTTAR, M.S. Lond., F.R.C.S.,

ASSISTANT TO THE RADCLIFFE PROFESSOR OF ROYAL SURGERY.

through it. On the forty-sixth day he left the hospital, being able to swallow both fluids and solids without any pain or difficulty, the external wound being almost healed. It is worthy of note that, a few days after the operation, the patient's voice was observed to be somewhat hoarse, and my colleague, Dr. Harris, who examined the larynx shortly before he left the hospital, reported that the left vocal cord was completely paralysed. This would indicate that the left recurrent laryngeal nerve was either injured during the operation or it afterwards became involved in the inflammatory exudation which would be poured out, probably in considerable quantity, in the neighbourhood of the wound in the gullet. When the patient was last seen, some weeks subsequently, the wound was firmly cicatrised, deglutition was perfect, and his voice was gradually improving.

The following remarks have been suggested by a consideration of the foregoing cases:—

1. *Question of operative interference.*—When the foreign body is of considerable size and irregular in shape, as in the case of a tooth-plate, and when it is so firmly fixed in the gullet that it resists all attempts at extraction through the mouth, œsophagotomy should at once be performed. If left in the hope that it may make its way onwards and be subsequently passed by the bowel, very serious results are liable to ensue, as Church has shown in a valuable paper published in the St. Bartholomew's Hospital Reports, vol. xix. The foreign body frequently causes ulceration of the œsophagus, and this complication is often followed by suppuration in the surrounding tissues or by fatal hæmorrhage, owing to the ulceration opening one of the adjacent large bloodvessels. The sooner recourse is had to operative interference, the more favourable will be the result; for if œsophagotomy is performed early—i.e., before inflammation and suppuration have supervened,—the operation is attended by much less risk than if some interval has been allowed to elapse. According to Fische,[1] the mortality is only 15 per cent. when œsophagotomy is performed within the first two days after the introduction of the foreign body; while, if delayed until the third or fourth day, it reaches 30 per cent.

2. *The operation.*—The operation is much easier of performance when the foreign body is situated in the cervical portion of the œsophagus (as in Case 1), and when it can be felt through the walls of the canal, as it forms a projection which can be cut down upon without the necessity of introducing any guide from the mouth. When impacted in the thoracic portion of the canal, and when the opening has to be made as low down as possible (as in Case 2), the exposure and opening of the œsophagus are much more difficult, especially if the neck is thick. Under these circumstances a full-sized bougie introduced through the mouth will probably be found a better guide than a pair of curved forceps or a sound, as usually recommended.

3. *Suture of œsophagus.*—As regards the question of suturing the opening in the œsophagus, this must be decided by the condition of the wound in its walls. If the margins of the wound are clean cut and free from bruising, it may be attempted, fine catgut sutures being employed; and under these circumstances there is a possibility of union at once taking place. If this happens, the wound in the overlying parts will more quickly heal, for the tissues to the neck will be kept free from the irritation of the saliva, which, as it is swallowed, tends to continually escape through the œsophageal opening when the latter is left unclosed. Care must be taken not to include the mucous membrane in the sutures, which should only pass through the muscular coat, for we know that in other parts of the body the divided mucous membrane does not readily unite, and if it becomes everted so as to fall in between the margins of the wound, its presence will interfere with repair. In most cases, however, it will be found that the œsophageal walls at the point of impaction will have become somewhat bruised and inflamed, the mucous membrane especially being lacerated, in consequence of the foreign body tearing and dragging upon it during the attempts previously made at extraction. Moreover, the actual removal of the body itself, if it is large and irregular, and when effected through a small opening, will be likely to conduce towards the same result. Under these circumstances the œsophageal wound is not likely to heal by primary union, and it was for these reasons that in neither of the preceding cases was suture attempted. This view is supported by a consideration of seven recorded cases where the œsophagus was sutured. In four cases[2] where the foreign body was removed through the wound, it proved unsuccessful. In three cases[3] primary union appears to have taken place, but in only one of these (Wright's) was the foreign body extracted; in Lediard's, it was not found at the time of operation, and in Lange's it was pushed onwards into the stomach, so that presumably in both these patients the margins of the opening in the œsophagus would escape the bruising and laceration which usually accompany the extraction of the foreign body, when of considerable size, and especially if sharp and irregular, as in the case of a tooth-plate.

4. *After-treatment.*—Owing to the difficulty of obtaining primary union, even if the œsophagus is sutured, and also of maintaining an aseptic condition of the wound in consequence of the escape of saliva through it, free drainage should be provided for by leaving the superficial wound partly open, and by inserting a tube, which should reach down to the opening in the œsophagus. When there is a copious discharge, as in both my patients, the wound should be syringed out with some antiseptic lotion (e.g., boracic), and the dressings changed frequently. The plan adopted of allowing the patients to frequently swallow small quantities of boracic mixture is, I think, also useful, for the greater part of the fluid at first escapes through the wound, and in this way thoroughly irrigates it from the bottom; at the same time it relieves the thirst from which the patients suffer, when no liquid food is being given by the mouth. By these means, though the discharge, which consisted of a mixture of frothy saliva and muco-pus, was somewhat profuse, the wound was in both cases kept in a fairly sweet condition, and there was never any tendency to the development of cervical cellulitis, a frequent complication of this operation, and one which is always liable to be attended by serious results.

5. *Administration of food.*—Inasmuch as it is not desirable to give any food by the mouth for some days, the feeding of the patient after œsophagotomy is always a difficult matter. It may be carried out in two ways—viz., nutrient enemata or suppositories may be administered, or food may be introduced directly into the stomach by means of a soft tube passed through the mouth, nose, or wound in the neck. If enemata can be retained by the patient, this method is preferable, for by keeping the wound free from the irritation caused by the passage of a tube, as well as from contact with any food regurgitated by the stomach, the parts are placed in the best condition for healing. In both cases the patients were fed entirely in this way for the first fortnight, the enemata, which were adminstered every four hours, being well retained, nothing being given by the mouth except boracic mixture and ice, as already mentioned. At the end of this period a tube was passed by the mouth (after the second day by the patients themselves), and at the end of three weeks, when the wound was nearly closed, the tube was discontinued, and the patients were allowed to swallow liquid food. It was then found that very little fluid escaped through the wound, the greater part passing onwards into the stomach; what did escape appeared to cause no irritation, probably owing to the fact that by this time the opening in the neck was converted into a fistulous track lined with a layer of healthy granulation tissue. If the enemata are not retained, food must of course be introduced much earlier into the stomach, and under these circumstances the passage of a soft tube through the mouth is, I think, for obvious reasons preferable to the method recommended by Markoe[4] of introducing it directly through the wound in the neck.

6. *Results of operation.*—According to Gross,[5] the number of cases of œsophagotomy recorded up to 1886 is 82; of these, 63 were successful and 19 terminated fatally. Since that date I have found reported in the different journals 14 additional cases, of which 10 were successful and 4 were followed by death. If the two cases above described are included, this will give a total of 98 cases, of which 75 were successful and 23 unsuccessful—that is to say, the operation of œsophagotomy is attended by a mortality of a little less than 25 per cent.

RECENT RESEARCHES RELATING TO THE ETIOLOGY OF YELLOW FEVER.

By GEO. M. STERNBERG,
SURGEON, U.S.A.

THE prerequisites to which I have engaged under instructions from the President of the United States, and in pursuance of authority of an Act of Congress approved March 3rd, 1887, "to enable the Secretary of the Treasury to investigate the subject of yellow fever, and to expend such sum as may be necessary for the expenses of the investigation," is not completed. The primary object of the investigation was to discover the specific exciting factor solely, and extended comparative researches as to the specific etiological relations of one or the other of the various micro-organisms found in the blood and tissues of yellow fever patients, to other diseases, principally from the intestines. Owing to the late period at which the investigation was undertaken, and the great field and many lines of research which it was necessary to cover, much of the time of the commission has been occupied in the preliminary work of collecting material, and in the study of the various micro-organisms associated with the intestinal disturbances which are so prominent a feature of the disease. The commission left Washington for Havana on the 15th of March last, and returned from the middle of March until May 1st of the present year, a period of about six weeks, during which time the material necessary for a thorough research by modern methods was collected. Of the 109 cases of yellow fever, typical cases of yellow fever, most of which occurred in the practice of Dr. Carlos Finlay, of Havana, and others in the city of Matanzas, 80 cases were made the subject of bacteriological examination, and in addition to these 29 cases of non-specific intestinal disturbances were examined. Before leaving this city, my colleagues and myself were indebted to the kindness of Dr. Finlay, the health officer of Havana, for the privilege of examining the bodies of patients in the hospitals in that city, and also in Matanzas, and for many courtesies and facilities in the prosecution of our work. Dr. Finlay has also contributed to the commission a valuable collection of cases of yellow fever patients. The blood-drawing and post-mortem examinations were made by myself and in a limited number of cases I have also obtained from the blood and tissues

minority which differ from these in very important particulars. They differ, indeed, so much as to have suggested our main question, Does albuminuria after scarlatina always represent one condition? I think, after considering a number of such cases and comparing them, it will be agreed that hitherto the idea of an inflammatory lesion of the kidney has been much too closely associated with the appearance of albumen in the urine; that is to say, there are many cases of scarlatinal albuminuria (I believe the majority of them) which are not accompanied by true Bright's disease. It has been during the last few years only that this has been shown to be true of the so-called functional albuminuria occuring independently of scarlatina. One of the most striking differences among these patients which a cursory examination presents is what one may call the albumen course—that is to say, the mode of commencement of this symptom, and the variation in the quantity of albumen from day to day. It is seen, for instance, that in one set albumen commences in large quantity, and then at once diminishes to *nil* with scarcely an interruption. In another set it commences with but a trace, and rapidly increases to a maximum, which is maintained until the death of the patient. It may be said, of course, that the nature of all these cases is the same: some get well and others go to the bad, just as in all diseases. But there is a difference in the time and mode of its incidence and also a difference in the course taken by the disease, which makes it more probable that there is a fundamental distinction between them. Classifying them according to these distinctions, the cases fall into three main groups; and in order to make more clear the remainder of these observations, I may say at once that the first group I take to own nervous and vascular causes; the second group causes even of a more general character, for they are accompanied either by a general collapse during the process of dying, or occurring in some curious relation to other phenomena, which are also probably due to vaso-motor changes. The third group are undoubted cases of inflammation of the kidney.

Group 1 is the largest, and contains twenty-one cases of the class with which we are most familiar. Albuminuria commenced from the thirteenth to the seventeenth day. At the onset the patients complained of malaise, and refused their food for twenty-four hours or so, but this was markedly of a temporary nature; as a rule, they felt quite well after the second day. It is important to note, as distinguishing them from those of the other groups, that the albumen commenced, as a rule, in large quantity, but that it had no sooner appeared than it forthwith began to diminish. This condition occurs, moreover, when the primary effect of the fever has passed off. Its onset is not accompanied by any other unfavourable symptom—i.e., there is no general condition of the system recognisable which may be suspected of having any important relation to it—a point which again distinguishes this group from the next. These cases (roughly three-fourths of the total) all recovered.

Group 2 contains four cases in which the albuminuria is more obviously due to general causes independent of nephritis than it is in the first group. Its onset is peculiar in three important respects: firstly, in the time of its appearance; secondly, in the albumen course—i.e., the initial quantity and its variation from day to day; and thirdly, in its relation to the general bodily condition. Instead of commencing in large quantity and at a period tolerably constant within a few days' limit, as in those of the first group, it appears in medium quantity and at no fixed time. The albumen course, instead of showing a gradual decrease as in the first group, or a gradual increase as in the cases of true inflammation of the kidney in the third group, varies very little from day to day, its quantity remaining steady from first to last. But the most significant circumstance which suggest for this group a class of its own is the relation which the albuminuria bears to the general bodily condition. There seems not the slightest doubt that the appearance of albumen depends upon general nervous and vascular conditions, and not upon nephritis. For instance, in the first case a trace of albumen appears simultaneously with copious effusion into an inflamed pleura; it remained but a trace, and disappeared permanently in three days. One and the same nervous disturbance in all probability was the cause of both these conditions; and further, if this is true, we have some light shed upon the nature of serous effusions. The second case is similar. Albuminuria commenced in the fourth week simultaneously with pulmonary œdema; it ran concurrently with this symptom, and terminated with it exactly. Both symptoms I believe to be associated with a low arterial tension caused by a protracted recovery of nervous tone. Group 2 contains also two fatal cases. In these we have patients dying in the fourth and fifth week respectively, exhausted by the violence of the fever. A few days before death, when the vital powers are rapidly waning, albumen appears in their urine. The quantity was small, and remained the same during the few days the patient lived. Does anyone suppose these were cases of Bright's disease? At the same time, too, there is copious watery diarrhœa and a low feeble delirium.

Is there not some connecting-link between these phenomena when they occur under these circumstances? I think they are all the consequences of a rapidly failing vitality. In the same way in regard to the first two cases of this group. Is there no physiological relation between the appearance of albumen, on the one hand, and the simultaneous onset of pleural effusion in the one case and pulmonary œdema on the other. I think it very probable that all these symptoms, including albuminuria when it occurs under these circumstances, are caused by a fall in the arterial blood-pressure below a certain standard. In many quarters it is too easily assumed that the passage from the blood of albumen in the case of the kidney, or of serous fluid in the case of the pleura, or of œdematous fluid in the case of the lung, or of the watery fluid in the case of the bowels, it is too easily assumed that the passage of these fluids through the vessel wall is brought about by a mechanical straining effected under an increased arterial tension. Is the process a vital or a purely physical one? I believe these phenomena most commonly occur with a diminished arterial tension. For instance, it is not in the congested state of the pulmonary circulation in mitral disease, when the pulmonary blood-pressure is increased, that we get œdema of the lungs so much as in conditions of systemic collapse and in cases where the tension in those vessels is diminished by a weak right heart; or when there is a mechanical blocking of its right chambers by thrombosis, such as we find after death in cases of malignant scarlatina or small-pox. Again, it is in the collapse of cholera that we get the copious watery stools simultaneously with failure of the urinary secretion, which physiolgically depends upon a proper blood-tension.

Summarising now the chief points which have guided our classification, we have in Group 1 the albumen appearing early when the patient is otherwise well. It is at first in large quantity, but at once diminishes, and the natural tendency is towards recovery. In Group 2 we find albuminuria due to general causes; either it is part of a general tendency to serous effusion or the like, or it is a symptom of failing vitality before death. In each case it probably depends upon a diminished arterial tension. In Group 3, in which it occurs in connexion with acute nephritis, the albumen commences as a trace and steadily increases. This classification can, of course, be only a temporary and imperfect classification, but I think the clinical differences between the groups warrant us in thus separating them. There is still other evidence in abundance that the influence of the nervous system in the majority of cases is of the first importance. The amount of albumen was always increased by any influence tending to lower the tone of the nervous system, and it invariably remained longest in those of a phlegmatic temperament or of a strumous diathesis. Passing disturbances of the system had a most instructive effect, always temporarily increasing the quantity of albumen, but not in the long run prolonging the symptom. One case I will mention in particular. I vaccinated a boy during the eighth week of albuminuria, whilst the amount of albumen remained steady at one-tenth. On the second day after there was nausea and anorexia, and the albumen had risen to one-fifth. Next day he was the same, with one-fourth of albumen. This relapse only altered the regular decline of the albumen course temporarily. Four days afterwards the amount was one-twelfth—i.e., probably, exactly what it would have been on this day had the patient not been vaccinated. Another coincidence of exactly the same kind occurred in the case of a convalescent patient who had an attack of quinsy during the course of albuminuria. Changes in the weather, too, have a constant and marked effect. I have noticed that a falling barometer with rain repeatedly caused a temporary increase in the amount of albumen, and took off the edge of the patient's appetite. Now the portion

MR. G. S. POPE ON PERSISTENT HÆMATURIA.

of the nervous system when disturbance or mentally constitution to its passage of albumen, and which is at the same time a symptom of disease of the kidneys, and probably also nervous system, of the kidneys alone, or of the nervous system alone, or of the kidneys and nervous system conjointly, is not always easy to answer. Of course, if the kidneys are primarily affected, but not attended by any other or those symptoms which we usually associate with Bright's disease, then the question is very easily answered.

Passing now to the practical aspect of the question, one of the first things to be done is to ascertain whether the albumen is that large set of the greatest use in the prognosis—namely, whether it is of renal origin or not. Now, as I have already said, I believe, in regard to the differentiation as a very large proportion of cases, that the microscope is of very little use. Of course, if we find casts, we may be pretty certain that the albumen is of renal origin; but, as I have already pointed out, we cannot always find casts, even when the albumen is undoubtedly of renal origin. Then, as to albumoses or deuteroalbumen, we have no certain test for them. Heat and nitric acid will not precipitate them, and the only test we have is the biuret test, which is not to be relied upon. Then, as to albumoses or deuteroalbumen in any way connected with the kidneys, I am not aware that any one has ever examined a case of renal disease for them. Moreover, I am not aware that any one has ever examined a case of renal disease for albumoses or deuteroalbumen in any way connected with the kidneys, I am not aware that any one has ever examined a case of renal disease for them. Moreover, I am not aware that any one has ever examined a case of renal disease for them. Moreover, I am not aware that any one has ever examined a case of renal disease for them. Moreover

was ordered for the constipation. This, while regulating the bowels, caused an improvement in the urine, which was maintained, but never got beyond a certain degree.—20th: Taking into consideration the marked ill effect of liquid extract of ergot, coupled with the fact that in summer the patient was somewhat improved, I now concluded that here there was some altered condition of blood-pressure, in all probability marked increase, which caused the red blood cells to be forced through the minute vessel walls into the secreting tubes, thence to be excreted, and therefore an effort was made to diminish this increased pressure. The bowels being regulated relieved the general congestion of the abdominal viscera, and now the patient was ordered two vapour baths a week. These were regularly taken.—27th: Patient feels better, and says he has more life in him. Urine much improved.—June 1st: The improvement in health and general spirits is marked. Urine clear, but in the lower one-fifth of the vessel there is a pinkish, flocculent mucous deposit. With the tincture of guaiacum and ozonic ether test the presence of blood can be demonstrated.—8th: Specific gravity of urine 1020; acid; no visible deposits; no indication of blood either chemically or microscopically. This is the first time since the present attack.—15th: Urine normal.—22nd: Urine normal; phosphatic deposits. The duration of hæmaturia from first to last has been a little over two years, seven months, and ten days.—August 14th: I saw the patient to-day. Says he never felt better in his life; is in excellent health and spirits. There has been no relapse, and his urine is still normal.

THE PHYSIOLOGY OF DREAMS.

BY FRANCIS E. CANE, L.R.C.P. & L.R.C.S. EDIN.

THE physiology of dreams is a subject of great importance, from its close relation to the pathological conditions of delirium and brain disease. But the many explanations of the cause of dreams which are found in the writings of physiologists and psychologists are all more or less unsatisfactory. A good *résumé* of these explanations may be found in the works of Sully, Carpenter, and others. Plato considered dreams as the dominant mental impulses or habits resulting from our daily feelings and thoughts. Aristotle wrote a treatise on dreams, and supposed that they are the impressions left on the mind and body by the objects of outward sense. He noticed that it seemed to thunder when a slight sound was produced within the ears, and that phlegm slipping down the throat of the sleeper suggested the idea of swallowing honey. Hippocrates and Galen made no advance on these theories. Nearer our own times, Descartes, Leibnitz, Kant, and Sir William Hamilton taught that we think and dream continually through sleep, although we frequently forget we have done so. Other authorities hold that dreams are not always present during sleep. Hobbes says that dreams all proceed from "the agitation of the inward parts of a man's body," which results in keeping the brain active. Schopenhauer considered that the impressions received from the internal regions of the organism are conveyed to the mind through the sympathetic system of nerves, and there worked into quasi-realities. Professor McKendrick calls dreaming a kind of physiological delirium. Dreams are frequently defined as revivals of former sensory impressions resulting from the action of an untrammelled or uncontrolled imagination, or as an undue excitability of the brain with a suspension of the will. These explanations, however, are all unsatisfactory in one or more aspects. They do not rationally account for the great rapidity of dream thought and for the sometimes orderly yet frequently incoherent arrangement and succession of events. They do not account for the variegated, grotesque, blended, and extravagant pictures upon which we gaze with a total want of surprise, impassively viewing scenes which would puzzle, bewilder, and shock us in our waking moments. They do not explain the great confusion in the order of time and space wherein widely remote events and places are brought together, and persons set in new relations to each other. They do not explain somnambulism and talking in the sleep, or why we sometimes dream the same dreams again and are frequently conscious that we are dreaming; the way in which the whole dream is often dominated by feelings of joy or terror; the way in which the various aspects of an object are exaggerated, so that the seemingly large, beautiful, or horrible becomes strikingly so. In these ways dreams take a firmer hold on us for the time being than waking realities, for although when awake we may consider dreams as unsubstantial and unreal, yet to the dreamer at the moment his imagined surroundings absorb his whole attention, and are consequently very real. Above all, the theories hitherto advanced fail to account for the light and colour or simulation of visual perception which form the main or striking feature of all or most dreams.

In order to form a more correct idea of what dreams are, we must remember that the human body is a complicated machine made up of numerous secondary machines in themselves composed of a most intricate molecular machinery. This organism is unified and controlled by the sensory and motor nerve filaments which communicate in leashes with the intellegism in the great central nervous "exchange" of the brain. It is ever changing from minute to minute in its molecular constitution, and these changes result in countless chemical reactions and physical transformations of energy. It is most delicately responsive to all its surroundings, and is presided over by the intelligism which has never been seen or analysed. This intelligism has impressed on itself what I may call a sensographic record of all that it has learned from the moment when the deep sleep of its embryonic existence was first broken by its birth into the external world of matter and of sense. This sensographic record is the only criterion by which the intelligism can judge of objects which are presented to it in the condition of sleep, because in that condition it is deprived of the physiological instruments for measuring size, form, intensity, distance, direction, position, and many-sided aspects. Sleep is a state of repairing time, in which the nervous system does not so easily convey messages either to or from the intellectual presiding principle, but requires a stronger external stimulus or greater mental effort to properly communicate along the full length of the nerve.

I wish here to show that all the phenomena of dreams are fully accounted for by the auto-sensations physiologically developed within the body, and which are sometimes increased by pathological or semi-pathological conditions, and modified by external impressions or stimuli. These auto-sensations are so numerous and so frequently developed that a large volume might be written to discuss them. Briefly considering what takes place in the human body while asleep, we find that there are actual and innumerable sounds, sights, and feelings which get partially conveyed to the intelligism, while that intelligism is deprived of its full means to test their nature. We have twitchings or spasms of muscular fibres, of muscles, and of groups of muscles. We have extensions and contractions of limbs, with the sensations of impediment likely to accrue from tight or overmuch bedclothing. We have painful conditions of muscles, nerves, and blood-vessels from awkward positions of the sleeper. We have the movements of the breathing apparatus; heart movements and sensations of beating arteries and distended veins; conditions of the sexual apparatus and states of different organs, such as distended bladder, overloaded stomach, and feeling of flatus in the bowels; sensation caused by entozoa. Sounds innumerable are developed by the heart and arteries and veins; by the mouth and nose, as in snoring, grinding of teeth, and working of saliva; by the whole breathing system; by the muscular susurrus all over the body; by the creaking of joints and clicking of tendons and ligaments; by flatus in the stomach and intestines, and many mechanical noises in the ears themselves. There are, besides, a host of molecular sounds which must be present, although usually not perceived. In the eye we have those extra-retinal entoptic phenomena due to opaque particles in the transparent media which, in our waking moments, frequently appear projected into space as drops, striæ, lines, twisted bodies, forms of grotesque shape, and black dancing spots, often mistaken by the ignorant or inexperienced for natural objects, such as flies, worms, or birds. As an intra-retinal appearance I may mention the way in which we can see the branches of vessels in our own retinæ under the form of "Purkinje's Spectre." Tastes and smells may also be originated and perceived during sleep. The external influences which are well known to affect the sleeper are noises, voices, touches, lights, and changes of temperature. We have here

Digitized by Google

matters of common experience which Mosso has scientifically confirmed with the plethysograph. To these may be added the electrical, barometrical, and hygrometric states of the atmosphere, which all contribute to cause moods, sensations, and feelings. Moreover, there are the numerous pathological conditions, such as hyperæsthesia or dysæsthesia of one or more nerves, sets of nerves, or branches. In the optic nerve these conditions cause photopsia or flashes of light, flames, sparks, and stars. Photophobia may be present in the blind eye. In the auditory nerve we have humming, buzzing, singing, ringing of bells, violent explosions, and even words or conversations. In the olfactory nerve and nerves of taste we have odours and flavours. Many of these pathological phenomena are simply the hyperæsthesic nerves picking up the physiogical sights, sounds, and sensations. The action, interaction, and varied modifying, physiological, or pathological impressions are sufficient to account for all that we experience in our dreams. The visual aspect of dreams, or how we see light, colour, and form, is thus, to my mind, made quite clear when we come to study the lights existing or developed in the organism. From the nature and composition of the body it is physically certain that they must be present. Phosphorus emits light; so do calcic sulphide, boric sulphide, chalk, silk, teeth, and other substances. The emission of light is one of the properties of protoplasm. Phosphorus enters largely into the composition of the human body, being present as phosphates in the bones and other tissues. It exists in muscle as a combination of phosphoric acid. It exists as a phosphuretted fat in the lecithin of blood-corpuscles and of nerve and brain tissue. As oxygen is being constantly conveyed to these phosphuretted tissues, light will certainly be generated. It would be interesting to know if a micro-photograph of the circulation could be taken after long exposure in darkness with a very sensitive plate. Pressure on the globe of the eye, even in the dark, will produce "phosgenes," which appear as flashes of light or pale luminous centres, with circles of one or more colours. These are also produced by electrical currents. In a dark room with our eyes closed, we see that area of dim light called "the proper field of the retina," and across which many people see dim moving figures and shades of colour, which blend and dissolve fantastically. This field gets gradually brighter the longer we abstain from viewing actual light. We have numerous examples in nature of organisms developing light within themselves. Many plants, including some cryptogams, are luminous. A large portion of animal nature is phosphorescent, of which we have familiar examples in the glow-worms and fire-flies. Mr. Hoyle, of the *Challenger* expeditions has written some interesting matter on this subject. The general phosphorescence of the sea is due to pyrocystis, peridinium, noctiluca miliaris, and other low microscopic forms in their countless millions. Certain animalcules found in the tropics give off phosphorescent particles so diffusive that a tumbler of water containing one will become completely illuminated. The bright spots we see at the sides and in the wakes of vessels are due to salpæ, medusæ, and copepods, or surface crustaceans. Other crustaceans, several families of annelids, some beetles, and many fishes are phosphorescent. The luminous round shining bodies found on certain fish contain in their interior little lenticular bodies like eyes, and are considered by some naturalists as true organs of vision, or accessory eyes. Some crustaceans have also these eye-like organs. The light given out by phosphorescent animals is usually pale bluish in colour, but red, green, and purple are noticed in some animals. A form of apendicularia has the power to change its light from red to green, and finally blue. The intensity of the light is not very great, that of the sea at its brightest being obliterated by very little moonlight. The nature of the light is always monochromatic. The causes of phosphorescence are probably various. Some animals get luminous from feeding on putrid phosphorescent matter. Dead and putrescent animals are frequently phosphorescent. This is well known in the examples of fish and molluscs. The human cadaver is occasionally phosphorescent, and Phipson in his work on "Phosphorescence," records instances where human beings have been phosphorescent while alive. This is the case in the rare condition of phosphoridrosis or luminous sweat, which is sometimes seen in the last stages of phthisis, in miliaria, and in persons who have eaten putrid fish. I have examined numerous records of phosphorus and fish poisoning, but find nothing about the character of the dreams except that delirium was sometimes present. Therefore, from the chemical reactions involved, from biological analogy, and from physiological and pathological facts, we have good reason to believe that there is actual light produced within the body itself. We know that heat in varying intensity is produced, and that electricity is also developed by muscular activity. The production of electricity is another of the properties of protoplasm. The galvanometer proves that there are electric currents in plants. In fruits with pips the current is from the stem to the bud; in stone fruits it is in the opposite direction. The gymnotus, the torpedo, and the silurus possess the power of giving strong electric discharges.

The physiological facts here reviewed go to prove that sleep is not a condition of the intelligism, but that the intelligism is ever ready to receive any impression conveyed to it, and has a power of being aware that objects resemble each other. In the sleeping condition it is presented with an ever-varying procession of complex impressions, any one of which may dominate the aspect of the others. These are imperfectly supplied by the nerves of hearing, sight, touch, taste, and smell. They are judged to be things which they resemble or suggest, and, with the changing material supplied, are continuously construed into a record of misinterpreted objects and events. In fact, the intelligism is doing what we sometimes half-knowingly experience when, in fog, or dusk, or darkness, we mistake objects for others which they seem like. We also sometimes do this with our full knowledge when we imagine picture forms in the glowing embers, or amid fantastic rock and mountain scenery, or in the clouds that float across the sky. We know, too, that long-forgotten names and persons and places will come to memory at the odour of a flower, the sound of a voice, or a strain of music such as we experienced long ago. When a great city is wrapped in the quiet of night, we begin to perceive many strange sounds and sights which escaped us in the busy hum and glare of day. When the body is wrapped in sleep, the intelligism is then free to notice the auto-sensations which come modified by partially transmitted external stimuli, and perhaps changed by pathological conditions. In sleep the mind is not engaged with thoughts, but with molecular processes, and these processes are the great factors in the etiology of dreams, delirium, and mental diseases.

Liverpool.

TOOTH EXTRACTION AND ITS ALTERNATIVES FOR THE RELIEF OF PAIN.

BY H. C. QUINBY, L.D.S.I.,
PRESIDENT OF THE MIDLAND BRANCH OF THE BRITISH DENTAL ASSOCIATION.

THE following remarks are intended as an earnest remonstrance against the practice of extracting teeth for the mere relief from pain, a practice which those country surgeons who are, by reason of distance from special dental aid, compelled to pay attention to the teeth of their patients seem to think is the only possible form of treatment, and therefore perfectly justifiable. I am aware that many who call themselves dentists are guilty of a still more extravagant waste of human teeth; often, I fear, prompted by a motive of self-interest, which ought to be a sufficient reason for striking their names off the register; but, while an appeal to these men—if, indeed, any appeal would influence them—would be more in place in the pages of the dental journals, those special journals do not, as a rule, come into the hands of general practitioners in medicine and surgery, and no country surgeon can do without his LANCET. I constantly hear of cases like this. "I got toothache while I was staying at such or such a place, and, as there was no dentist near, I went to the doctor, and he took the tooth out." There is never any mention of an effort to save the tooth, and in these days, when surgery is making such rapid advancement in every direction, it is time that such empiricism should come to an end. I doubt if there is any other organ possessing a tithe of the functional importance to the maintenance of human health and strength that rightfully belongs to a grinding tooth which would not receive far more consideration if it were a

Digitized by Google

source of pain than any surgeon ever thinks of giving to a tooth.

When a tooth aches, the first suggestion is to have it out. But I do not hesitate to say, after many years of experience, that it is never necessary to extract a tooth merely for the relief of pain. That there may be, and are, many other reasons of sufficient importance to justify extraction I of course admit, and these should have proper consideration in cases of toothache: but what I mean to say is simply this: there are two forms of pain arising from teeth, which will include at least 90 per cent. of all the cases that will come to a dentist in good practice; we will call these primary and secondary toothache, and I contend that in neither of these is extraction ever the remedy to be chosen without careful deliberation.

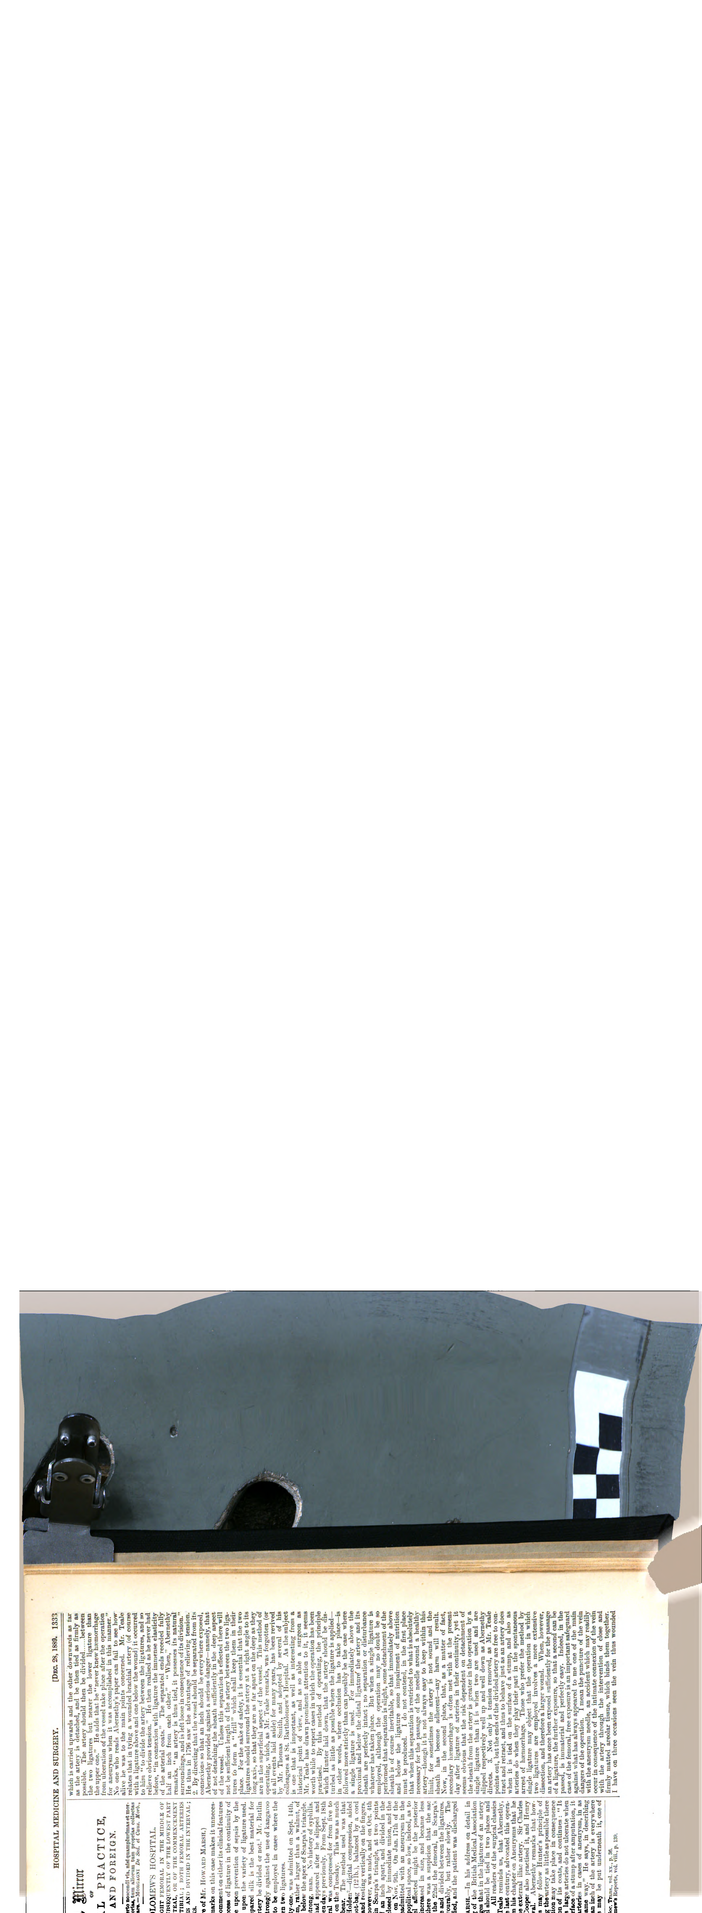
Primary toothache is congestion of the tooth pulp; the unyielding walls of the pulp cavity permitting no expansion, there is intense pressure on the nerve tissue, and consequent pain, which finally terminates by strangulation of the pulp. This is true toothache, arising in the tooth, but it may be felt in the terminals of any of the branches of the fifth nerve on the corresponding side of the face, and is rarely felt in the tooth where it originates, unless there is suppuration in the pulp, in which case the peridental membrane will be affected. It will be obvious that many cases of so called neuralgia in the face are simply toothache, and a careful search will generally reveal the offender, but there will be no occasion for extraction. Careful excavation, sufficient to allow an escape of blood from the pulp, will at once relieve the pain, and an arsenical dressing will devitalize the pulp, and there need not be anything like the pain of extraction. To complete the operation, the pulp must be removed from the root canals, and these filled to the apex; but this will call for special skill, and no harm will be done if there should be three or four weeks of delay. Nothing in a dentist's experience is more melancholy than to look into a mouth and see six or eight detached grinding teeth without an antagonising tooth in the opposite jaw.

The secondary form of toothache is usually admitted by the sufferer to be toothache, because the pain appears to be intensified by occlusion with an opposite tooth and by pressure of any kind. In reality the pain is caused by gangrene of the pulp, and I am quite aware that this is considered so serious a matter that most surgeons would order immediate extraction, but it is not at all a necessity. It is a matter of every-day practice with me and with thousands of other dentists to treat alveolar abscess successfully and make the teeth useful and comfortable. There are failures of course, as in everything else, but they are not more than one in ten, and of these half at least are failures only so far as this, that the abscess has established a sinus, and that for some time after the tooth has been filled there is an occasional discharge of pus from this sinus; but the cause of the diseased condition is removed, there is little if any pain, and the discharge ceases after a time. The first treatment is a very simple matter. Percussion indicates a diseased condition outside the tooth—that is, in the peridental membrane, and the cause is a decomposing pulp or some other putrescent matter in the pulp cavity. The tooth is generally decayed, so that a very slight excavation will open the pulp cavity and give vent to the poisonous gases and pus which are confined there, and when these find an outlet the pain ceases. Recognising the fact that alveolar abscess does not, and cannot, arise from a tooth which has a healthy pulp, it is obvious that an opening into the pulp cavity will be a painless operation, which, of course, extraction would not be, nor will extraction give relief so quickly as the simple treatment I have suggested. I do not mean to say that the soreness which was felt on pressure will immediately disappear; it will take time for that; but the intensity of the pain will be mitigated, the contents of the abscess will be evacuated through the roots of the tooth, and very quickly the tooth will be in a condition for further treatment, which will in most cases result in a radical cure of the tendency to abscess, and the tooth will be made useful and comfortable. The course of treatment is a series of antiseptic dressings in the roots to cleanse them from all putrescent matter, and then, as in the other case, filling them to the apex, for while abscess is first caused by toxic matter from the decomposing pulp, it is maintained and renewed by the filling up of the pulp cavity with pus and lymph, which in their turn pass through the same process of decomposition. This root treatment, however, is not available in temporary teeth after the sixth year, as the process of absorption which is going on in the roots of these teeth will have so widened the apical foramina that a solid filling cannot be made, and is therefore worse than useless; but it is better to open the pulp cavity freely and leave it open, so as to allow free evacuation into the mouth and allow the tooth to decay gradually, as it will of course do, until nothing but the roots remain, than to deprive the child of a masticator at once.

The child needs masticators quite as much as the adult; but, more than this, I am certain that it is almost an impossibility to extract the temporary molar when it is in anything like full development without more or less displacement of the partially developed bicuspid which lies between the roots of the temporary molar. I am well aware that it has been said over and over again by writers who are recognised as authorities that the development of the alveolus of the bicuspids does not depend on the retention of the temporary teeth; but what does that matter if the partially calcified crown of the bicuspid is so displaced that the further development goes on with the tooth in a transverse or a horizontal position? I have in my possession models of the upper and lower jaws of a boy of ten years and a half of age, whose temporary molars and two canines were all taken out while in almost perfect development, and the gums are shrunken like those of an old man, with not the slightest indication of a bicuspid appearing for the next five years. I often see cases where some of the temporary molars have been removed, but I confess I do not often see cases of such wholesale premature extraction.

Alveolar abscess may arise from a putrescent pulp in a tooth which is not decayed at all, but which has some time been displaced by accident so as to sever the nerve and bloodvessels at the apical foramen. This happens, especially with front teeth, from a fall, from a blow, from many chances in athletic games; and often enough the tooth may be comfortable for months after the accident, so that no one thinks of connecting the present pain with what happened so long ago, but by drilling into the pulp cavity the poisonous gases and the pus are evacuated, and the tooth can be made as useful as the others. In all cases after a front tooth has been loosened by an accident it should be watched carefully for a few months to see if any change of colour takes place, and if so the pulp cavity should be opened at once.

Pyorrhœa alveolaris may cause something very like alveolar abscess, and yet the pulp of the tooth will retain its vitality; but in this case the disease commences at the neck of the tooth and proceeds towards the apex of the root, which is exactly the reverse of what happens when there is a putrescent pulp. In these cases, although relief will be given by a thorough cleansing of the root, by scraping, and by one or two applications of aromatic sulphuric acid, followed by soothing dressings, there is little chance of saving the tooth for more than a year or two.



In this paper I have only meant to indicate that there are means of relieving the ordinary forms of toothache, which will be far more merciful than extraction, to the patient, and which are so simple that any surgeon can make use of them, and at least, if he cannot complete the operation, he will have relieved present suffering, and left the tooth to be treated by hands which have had more practice. But I do not by any means pretend to have exhausted the subject, or to have presented anything which will be new to dentists. I am told that surgeons do not learn these things from their text-books, and I hope I have shown them that there is something more interesting about teeth than extracting them.

Liverpool.

BEQUESTS AND DONATIONS TO HOSPITALS.—The late Col. George Tomline, of Carlton House Terrace, London, and Orwell Park, Ipswich, bequeathed £100 each to the East Suffolk Hospital and the Convalescent Home at Mablethorpe. The City of London Common Council has granted 100 guineas each to the Royal Sea Bathing Hospital, Margate, and the Metropolitan Provident Medical Association. The late Earl of Leven bequeathed £2000 to Convalescent Homes, and £2000 to the British Orphan Asylum (Slough), and the Hospital for Sick Children; also £1000 to the Hospital for Consumption, Brompton. The Mercers' Company has granted donations to the following London hospitals—Guy's, £1000; Middlesex, £1000; London, £1000; and St. Mary's, £1000; King's College, £500; and Westminster, £500.

Hunter HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Ligature of Arteries in Continuity.

Under the care of Mr. HOWARD MARSH.

Ligature of the Femoral Artery in the Middle of Scarpa's Triangle.

Under the care of Mr. BARTHOLOMEW'S HOSPITAL.

Aneurism of the Right Femoral in the Middle of Scarpa's Triangle; Ligature of the Artery in Two Places; Gangrene of the Leg; Operation; Death.

Under the care of Mr. HOWARD MARSH.

(Reported by Mr. MAYO.)

The two cases of ligature of arteries in continuity recently performed at St. Bartholomew's Hospital, and recorded in our last number, have naturally excited much interest in the profession, and have led to a discussion of the question in the Medical Society of London. As the cases are of great importance, and as the operations are likely to be frequently performed hereafter, we have thought it desirable to give a full account of them, and of the discussion which followed the reading of the papers. We have, therefore, obtained from Mr. Howard Marsh and Mr. Mayo, the surgeons who performed the operations, full reports of the cases, and from Mr. Holmes, the President of the Society, a report of the discussion. We have also had the advantage of hearing Mr. Holmes's remarks on the subject of ligature of arteries in continuity, and of seeing the specimens which he exhibited to the Society. We have also had the opportunity of examining the specimens which were removed from the patients who were operated upon at St. Bartholomew's Hospital, and which are now in the museum of that institution. We have also had the opportunity of examining the specimens which were removed from the patients who were operated upon at St. Bartholomew's Hospital, and which are now in the museum of that institution.

The first case was that of a woman, aged 45, who was admitted into the hospital on Sept. 14th, 1868, with an aneurism of the right femoral artery in the middle of Scarpa's triangle. The tumour had been present for about three months, and had increased rapidly in size during the last few weeks. The patient was a stout, healthy woman, and there was no evidence of any disease of the heart or arteries. The tumour was pulsating, and a distinct bruit could be heard over it. The limb was cold, and the pulse at the ankle could not be felt. The patient was placed under the influence of chloroform, and Mr. Howard Marsh proceeded to tie the femoral artery in two places, and to divide it between the ligatures. The first ligature was applied about two inches above the upper end of the tumour, and the second about two inches below the lower end of the tumour. The artery was then divided between the ligatures, and the wound was closed with sutures and collodion. The patient was then removed to bed, and the limb was wrapped in cotton wool. The patient recovered from the operation without any untoward symptoms, and the wound healed by the first intention. On the fifth day after the operation, however, the patient complained of pain in the limb, and it was found that the foot was cold and the pulse could not be felt. On the following day the pain had increased, and the foot was still colder. On the seventh day after the operation the patient died.

On examining the limb after death, it was found that the femoral artery had been tied in two places, and that the portion of artery between the ligatures had been divided. The ligatures were found to be firmly fixed in the artery, and the ends of the vessel were closed by coagula. The tumour was found to be filled with clot, and the sac was ruptured at its upper part. The vessels of the limb were found to be healthy, with the exception of the femoral artery. The popliteal artery was found to be pervious, and the anterior and posterior tibial arteries were also found to be pervious. The veins of the limb were found to be healthy, with the exception of the femoral vein, which was found to be thrombosed. The muscles of the limb were found to be pale and flabby, and the nerves were found to be healthy.

The second case was that of a woman, aged 50, who was admitted into the hospital on Sept. 14th, 1868, with an aneurism of the right femoral artery in the middle of Scarpa's triangle. The tumour had been present for about three months, and had increased rapidly in size during the last few weeks. The patient was a stout, healthy woman, and there was no evidence of any disease of the heart or arteries. The tumour was pulsating, and a distinct bruit could be heard over it. The limb was cold, and the pulse at the ankle could not be felt. The patient was placed under the influence of chloroform, and Mr. Howard Marsh proceeded to tie the femoral artery in two places, and to divide it between the ligatures. The first ligature was applied about two inches above the upper end of the tumour, and the second about two inches below the lower end of the tumour. The artery was then divided between the ligatures, and the wound was closed with sutures and collodion. The patient was then removed to bed, and the limb was wrapped in cotton wool. The patient recovered from the operation without any untoward symptoms, and the wound healed by the first intention. On the fifth day after the operation, however, the patient complained of pain in the limb, and it was found that the foot was cold and the pulse could not be felt. On the following day the pain had increased, and the foot was still colder. On the seventh day after the operation the patient died.

On examining the limb after death, it was found that the femoral artery had been tied in two places, and that the portion of artery between the ligatures had been divided. The ligatures were found to be firmly fixed in the artery, and the ends of the vessel were closed by coagula. The tumour was found to be filled with clot, and the sac was ruptured at its upper part. The vessels of the limb were found to be healthy, with the exception of the femoral vein, which was found to be thrombosed. The muscles of the limb were found to be pale and flabby, and the nerves were found to be healthy.

The third case was that of a woman, aged 50, who was admitted into the hospital on Sept. 14th, 1868, with an aneurism of the right femoral artery in the middle of Scarpa's triangle. The tumour had been present for about three months, and had increased rapidly in size during the last few weeks. The patient was a stout, healthy woman, and there was no evidence of any disease of the heart or arteries. The tumour was pulsating, and a distinct bruit could be heard over it. The limb was cold, and the pulse at the ankle could not be felt. The patient was placed under the influence of chloroform, and Mr. Howard Marsh proceeded to tie the femoral artery in two places, and to divide it between the ligatures. The first ligature was applied about two inches above the upper end of the tumour, and the second about two inches below the lower end of the tumour. The artery was then divided between the ligatures, and the wound was closed with sutures and collodion. The patient was then removed to bed, and the limb was wrapped in cotton wool. The patient recovered from the operation without any untoward symptoms, and the wound healed by the first intention. On the fifth day after the operation, however, the patient complained of pain in the limb, and it was found that the foot was cold and the pulse could not be felt. On the following day the pain had increased, and the foot was still colder. On the seventh day after the operation the patient died.

On examining the limb after death, it was found that the femoral artery had been tied in two places, and that the portion of artery between the ligatures had been divided. The ligatures were found to be firmly fixed in the artery, and the ends of the vessel were closed by coagula. The tumour was found to be filled with clot, and the sac was ruptured at its upper part. The vessels of the limb were found to be healthy, with the exception of the femoral vein, which was found to be thrombosed. The muscles of the limb were found to be pale and flabby, and the nerves were found to be healthy.

during the operation for ligature of the femoral artery. The method by double ligature and division may, I believe, be employed with advantage in the case of all the arteries which can be exposed for a sufficient length. The subclavian, however, in some instances is so deeply placed that the proceeding could not be safely carried out. But in any case in which, rising fairly into the root of the neck, the vessel could be cleared for three-quarters of an inch, there appears no ground for refraining from dividing it between two ligatures. While, since it is this artery above all others which is liable to secondary hæmorrhage after ligature, it seems incumbent on the surgeon to adopt, in tying it, any measure by which this highly dangerous accident may be rendered less frequent. Many may shrink from dividing the artery through the fear that the ligature may slip. Here is a danger which, of course, must be most carefully guarded against. Yet it is difficult to see how the ligature is more likely to slip in the case of this vessel than it is in the case of the femoral or the external iliac. This danger is to be obviated, first, by the use of a ligature which, when it is tied, will have a firm "bite" on the vessel. The ligature employed in the cases related above was a carefully selected kangaroo tendon of medium size. I should also consider either carbolised silk or a large-sized chromicised catgut ligature suitable and trustworthy. The wide ox-aorta ligature should not be used, for it cannot be drawn tightly enough to obtain the necessary "bite." Secondly, the ligatures must be placed at a distance of three-quarters of an inch from each other, and great care must be taken that this space is secured behind as well as in front of the vessel. If, when the artery has been divided and the relations of the ligatures examined, there is any doubt about the security with which the ends of the artery are closed, another ligature ought to be applied, just as it might be in the case of an artery tied on the face of a stump. So far as I have been able to ascertain all the cases in which this method has been employed (including two instances besides those related above in which I have tied the femoral) at St. Bartholomew's Hospital since Mr. Smith revived it have been satisfactory, with two exceptions. In one of these the ligature slipped from the subclavian.[3] In the other the carotid was tied in the receiving room by one of the house-surgeons under circumstances of considerable difficulty. Here also the ligature slipped. I regard these cases as warnings rather than as evidence against the principle of the operations of double ligature and division. In the subclavian case a kangaroo tendon was employed, and the operator remarks that this form of ligature exerts a less secure hold on the vessel than would be the case with silk. There seems no objection to the use of carbolised silk; but there are now so many cases in which kangaroo tendon has been used without accident that it is the material which I should be inclined to select.

KASHMIR MISSION HOSPITAL.

A CASE OF FRACTURE INTO THE KNEE-JOINT; ARTHRECTOMY; NECROSIS; RECOVERY; REMARKS.

(Under the care of Mr. A. NEVE.)

THIS case presents many features of interest, not the least of which is its resemblance to that of an acute epiphysitis of the lower end of the femur, with secondary involvement and disorganisation of the knee-joint. In carrying out the principle of conservatism which should guide all surgeons, the operation of arthrectomy undoubtedly aided greatly in saving the limb; but it is not surprising that it was found impossible to render the part fully aseptic when the condition of the parts on admission is considered. Although the operation of arthrectomy is most successful in a joint the subject of synovial disease without sinuses, this case is a good example of its ultimate success under somewhat unfavourable circumstances.

A Kashmiri girl aged two years and a half fell and fractured the right femur above the condyles; she was brought to the hospital twenty-two days later, at which time the region of the knee was much swollen and inflamed, and there was a large sinus behind, leading to the edge of the fractured bone. This sinus was large enough to admit the finger, which felt bare bone, and a probe could be passed into the knee-joint. The discharge was considerable.

[3] Clin. Soc. Trans., vol. xx., p. 34.

First operation.—On Aug. 26th, 1889, the joint was freely opened by a curved incision, all the pulpy synovial membrane removed, and a thin slice taken from the cartilaginous surfaces. At the seat of fracture a bared projection of the upper fragment was clipped off. Drainage was arranged through the old sinus, the joint closed, and immobilised with an iron splint and plaster-of-Paris. In a few days there was great discharge of pus, and the anterior wound began to open. Within twelve days the whole line of union broke down and the condition of the part looked very bad.

Second operation.—On Sept. 7th the patient was placed under chloroform and the wound examined, a sequestrum the size of the kernel of a walnut was removed from behind the condyles. Opening up the whole knee-joint, it was found that the lowest portion of the external condyle was separated—an almond-shaped piece of cartilage, with one surface concave. There were several small scales of necrosed cartilage on other parts of the condyles, but the tibia was covered with healthy granulations. The flap was reapplied with deep wire sutures, and a posterior splint fastened on. After this healing proceeded rapidly. The flap united at once, and the sinus behind granulated up, with daily decreasing discharge. On Oct. 1st the patient left the hospital cured.

Remarks by Mr. NEVE.—It is noticeable with what rapidity this little patient ran through the successive phases of suppuration, sequestration, and granulation. It certainly appeared as if the arthrectomy determined the necrosis. If so, the separation was complete within the incredibly short period of twelve days. The result was fortunate; but if the mother had declined a second operation it would have been disastrous. On the other hand, an expectant method of treatment, or treatment by simple joint drainage, had little chance of success, and the patient would have been taken away before the disease had been cured. In European private practice the indications might have been different; but if a similar case presented itself here I should be impelled to the same method of treatment.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

Mitral Stenosis in Children.—Cerebral Abscess after Middle Ear Disease.

AN ordinary meeting of this Society was held on Dec. 23rd, the President, Dr. C. Theodore Williams, being in the chair.

Dr. A. E. SANSOM read a paper on the Pathological Anatomy and the Mode of Development of Mitral Stenosis in Children. The paper was founded on forty cases clinically observed and nineteen post-mortem examinations, all in children of twelve years of age and under. In regard to *morbid anatomy*, mitral stenosis in its least pronounced degree was evidenced by a ring of granulations around the mitral aperture on its auricular aspect; these vegetations might be friable and fibrin-covered, or fibrous and firmly fixed. The subjacent structures were firmer than normal, and formed a thickened ring. The thickening might further involve the curtains, cords, and columns of the mitral valve. In the more pronounced stenoses the mitral curtains were fused to form a funnel, the ventricular aperture of which might be of varying degrees of patency to the dimensions of a crowquill. In the child funnel-mitral was to buttonhole in the proportion of 8 to 1, while the buttonhole form was the most frequently observed form in adults. The left auricle was often greatly hypertrophied or dilated; its wall might be a quarter of an inch in thickness, or it might be dilated extremely and its wall very thin. The left ventricle was usually of normal or subnormal dimensions; when enlarged it was usually in association with general hypertrophy of the heart and pericarditis. The right chambers were almost invariably dilated. Mitral stenosis was *not a congenital malformation*. It was observed in one case of congenital anomaly, but then it was distinctly the result of fœtal endocarditis. It was extremely rare under the age of five years, and might be considered as invariably the result of endocarditis. In every case examined post mortem there was an association with endocarditis, pericarditis, or both these affections combined. In regard to etiology, the cases showed a very strong associa-

The abscess arose probably from infection by way of the lymphatics, though some of these cases might perhaps be looked upon as instances of cerebral lesion by sympathy.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Hospital Operative Practice.—Bladder Growth.

A MEETING of the above Society was held on Friday, Dec. 6th, Dr. H. Campbell Pope, President, in the chair.

Mr. BRUCE CLARKE read a paper on Nine Years' Experience of his Operative Practice at the West London Hospital. He exhibited a table of 296 operations of various kinds, most of them so-called major operations, with a mortality of ten cases, only four of which were to be ascribed to the operation. The six which, as he explained, died of the disease rather than the operation included cases of hernia and intestinal obstruction, which were practically moribund on admission, whilst the four which died from the operation were—a tumour of the bladder, a tumour of the prostate, a nephro-lithotomy, and a case of radical cure of hernia. The table was divided into sixteen sections, beginning with thirty-nine tumours, without a death. Then came amputations: eighteen with two deaths, both due to gangrene, for which they were performed, and which returned in the stump and terminated their existence some few hours after operation. Twenty-eight cases of opening of joints were recorded, in which all but one recovered with good movement, and some sixty cases in which the peritoneal cavity was explored, in which, if the acute cases before referred to as being moribund on admission were excluded, only one death had taken place, and that was the case of radical cure of hernia. Amongst the cases of great interest were over a dozen kidney operations, seven lithotrities, and thirteen cases of cystotomy, two large stones from which were exhibited. A large series of pathological specimens illustrative of the cases were exhibited from the museum of the hospital by Mr. Dunn. Mr. Bruce Clarke said, in conclusion, that he recorded in the paper all the cases of operation which had been under his care except a few of the slighter cases, and in these no deaths had occurred. Amongst other points to which he drew attention was the fact that in no single instance had he amputated a limb in consequence of a joint lesion, acute or chronic. Perhaps nothing revealed so clearly what a vast difference there was between the surgery of to-day and that of five-and-twenty years ago as the progress that surgeons had made in the treatment of joints.—The PRESIDENT thought that Mr. Bruce Clarke's mortality of 3½ per cent. after operations was a very low one.—Mr. EDWARDS remarked on the large percentage of cases of urethrotomy (4 out of 21), and said that in his experience it was rare that means could not be found to introduce a very fine bougie.—Mr. BRUCE CLARKE replied.

Mr. HURRY FENWICK described an Unusual Recurrent Bladder Growth. He showed wax models of growths in the bladder of a lady aged forty-three. The patient had come under the care of Dr. Oldfield, suffering from hæmaturia of two years' duration. On introducing the electric cystoscope a hazel-nut-sized cancerous growth was seen overlapping the mouth of the left ureter, the rest of the bladder being perfectly healthy. A model was made of its appearance. The urethra was dilated, and the tumour, which was found to possess a long pedicle, was snared and cut off with scissors. Microscopically it proved to be a villous-covered carcinoma. After six months' complete rest the symptoms recurred, and two months later the cystoscope was introduced. The scar of the operation was seen to be perfectly healthy, and the cause of the bleeding was found to be another tumour on the opposite side of the bladder behind the right ureteral opening. There were two small satellite splashes of growth in the neighbourhood of the principal tumour. All three were carefully dissected off the bladder-wall, and the patient made a good and rapid recovery. The second growth was shown to be benign. The unusual features of the case consisted in (1) a bladder cancer being pedunculated; (2) a bladder which had already developed a cancer, subsequently forming an innocent growth; (3) the formation of satellite villous growths in the neighbourhood of the benign tumour. It was contended that this little group of irritative growths demonstrated the existence of some permanent irritation in the bladder.—Mr. BRUCE CLARKE thought that the second tumour must already have begun growing before the first was removed.—Mr. KEETLEY referred to the numerous small warts on some persons in whom only one would sometimes take on malignant growth.—Mr. FENWICK, in reply, dwelt on the coexistence of benign and malignant growths in the same individual.

Mr. PERCY DUNN exhibited specimens of Impacted Calculi in the Urinary Bladder and a Tumour of the Thyroid.

Mr. EDWARDS showed a case of Distension of the Abdominal Veins.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

THE opening meeting of the Medical Section was held on Nov. 15th, when the PRESIDENT (Dr. Atthill) made some appropriate remarks.

Morphinism.—Dr. FOOT read a paper on this subject, and drew attention to the increasing prevalence of the use of the hypodermic syringe as a medium for the vicious introduction of morphine into the system. Morphinism (a word introduced by Levinstein) was, in some parts of Europe, at present almost a matter of fashion: gifts of handsome syringes in silver cases were exchanged on festive occasions, and reciprocal injections of morphine made on favourable opportunities. The subject was one of special interest to medical men, because of the number of their colleagues who had fallen victims to it. Some said this was a just retribution upon those who were responsible for the practice. Dr. Foot thought it more charitable to attribute the habit to (1) the relief of pain, (2) insomnia, (3) melancholia, (4) curiosity, or (5) imitation. A receptivity for morphine was not possessed by everyone; all its effects were unpleasant to many. Few morphinists were satisfied with less than three grains in the twenty-four hours; many used more than ten times that amount. The diagnosis or detection of the morphine habit was discussed, and stress laid upon the peculiar untrustworthiness of the patient's own statements as to the amount or frequency of the dose. The prognosis in morphinism was not at all favourable; the probability of a cure might be estimated by attention to the following points: the duration of the habit, the persistence or not of the exciting cause, and the physical and nervous constitution of the patient. Relapses were very frequent; successful treatment, unless under the most favourable circumstance, was hardly possible in the patient's home. As to the treatment, emancipation from morphine slavery was unattainable by voluntary effort. The process of cure, or of demorphinisation, required more moral and physical courage than was at the disposal of a morphine *habitué*. The treatment was considered under the heads of the deceptive plan, the substitution plan, the tapering-off plan, and the abrupt withdrawal plan. The first two methods were not to be seriously considered in the treatment of confirmed morphinism. The tapering-off plan involved prolonged misery during the weaning process. The abrupt plan was frequently followed by a dangerous group of symptoms. A modification of the latter two methods might be adopted—the complete withdrawal of the morphine, not abruptly, but in from six to twelve days.—Dr. FALKINER mentioned the case of a school teacher whom he saw take five ounces of laudanum at a draught, and afterwards gave up the habit.—Dr. EUSTACE advocated the abrupt and sudden total withdrawal of the drug in morphinism, and of the spirits in alcoholism, as the best and most scientific treatment. As a rule, only a partial cure was effected, for sooner or later temptation led to a relapse.—The PRESIDENT'S experience led him to advocate gradually diminishing doses. He knew a medical man who took one-sixth of a grain four or five times in the twenty-four hours, and who had the firmness not to exceed that dose.—Dr. WALTER G. SMITH said it was difficult, in regarding the action of drugs of a certain class on the higher parts of our nervous system, to restrict consideration to any particular drug, such as morphine, without taking into account also the effects of other drugs of allied action. Thus there were two groups which might be arranged in the ascending scale of action—one the alkaloids, and the other the members of the fatty series, including chloral, ether, alcohol, &c. Dr. Foot had adverted to this class distinction, indicating that the prolonged use of one of the

Digitized by Google

members of the fatty series was liable to induce general tissue change and lead to death, whereas members of the alkaloid series affected chiefly the higher or psychical, emotional, and intellectual nerve centres, causing death by their action on the respiratory and cardiac centres. It was puzzling to reflect how some could take with impunity hundreds of times more morphia than would kill an ordinary person. There was a difficulty in this question, to which unsatisfactory answers could yet be given beyond the region of vague speculation. With regard to the question of how much or which any amount of discomfort or suffering could be excluded on the patient's part was a good reason for objecting to the sudden total withdrawal of the drug,—Dr. JAMES LITTLE did not believe in dis regarding the horrible torture, the intolerable suffering, produced by sudden total withdrawal, on the contrary, he thought the nervous system of the patient never recovered entirely from the wreck of misery and wretched ness produced by such treatment. For his own part, he had seen patients get on very well by gradually stopping the drug. The plan Dr. Foot had mentioned was the one which he had always adopted—namely, the gradual diminution of the drug. With regard to limitations, if a man was otherwise in perfect health, alcohol, and perhaps morphia too, might be stopped altogether; but in the case of the patient had chronic illness, even a catarrh, or anything else, however trifling, the smallest thing, he would be exposed to terrible risk by suddenly stopping either alcohol or morphia.—Dr. Sir. FOOT, in replying, said he thought Dr. Eustace had given the keynote to the discussion. There were two classes of cases to be considered. Thus Claudius drew a distinction between what he called morphinism and morphinomania—the former being the state of a person who had recently acquired a taste for morphia, whether from temptation, emulation, curiosity, or for relief of pain; and the latter the condition of mental deterioration only known to exist in those with such a craving, insufferable hunger that destroyed body and soul. The morphinomaniac in his periods of satisfaction would be in his condition, but would otherwise have no real desire to be cured, and would not know the first opportunity of getting rid of his craving, being practically insane and treated as a lunatic. On the other hand, the morphinist wished to be cured, and would assist in carrying out the graduated or tapering-off plan, which was the advisable treatment in such a case; for experience showed that total withdrawal was followed by what the Germans called *abstinenz symptome*, or reactionary efforts, which had sometimes proved fatal.

Notices of Books.

The Immediate and General Treatment of Accidents and Injuries. By Sir W. MOORE, K.C.I.E., M.D. Published under the authority of the Government of Bombay. Pp. 94. London: Churchill. 1889.—This work is of the nature of the somewhat numerous handbooks which treat of "First Aid to the Injured," but differs from these in an important point, that it has been prepared by the officer who held lately the appointment of Surgeon-General with the Government of Bombay, for use in India, and translation into the vernacular. It appears well adapted for the purpose, the instructions being generally clear and easily understood. On one point, however, in connection with the transport in cases of accidents and injuries, he differs entirely from the best authorities on the subject. After stating that a hurdle, shutter, door, or charpoy may be converted into a litter, he says: "The shutter or hurdle should be carried by the hand, and the bearers should 'keep step' to avoid shaking." But on this point Surgeon-General Sir T. Longmore in his excellent 'Treatise on the Transport of Sick and Wounded Troops,' lays down the rule that "The front and rear bearers of the conveyance must start with opposite feet. They must not move 'in step,' but, on the contrary, must march out of step, or, as the ordinary expression is, must 'break step.' . . . it becomes one of the first lessons in the instruction of men whose duty it is to carry sick and wounded. . . . The reason which dictates the rule I have named is readily apparent on examination. . . . There is no lateral movement giving the patient a tendency to roll from side to side." This is the rule laid down in all the books on ambulance work with which we are acquainted. We think that the author does not give sufficient prominence to the importance of promptly obtaining skilled medical or surgical aid in all cases of serious injury or illness. There is a great tendency to rely entirely on the assistance afforded in the first instance by ambulance pupils and others who have been instructed in the "first aid" to be given in accidents. Much valuable time is consequently often lost in serious cases, and, need we add, with unfortunately irremediable consequences. It may be that in many places such assistance is not within reach or could only be obtained with much difficulty and delay, but it is none the less desirable that the importance of procuring it, when possible, should be clearly indicated.

Clinical Lectures on Varicose Veins of the Lower Extremities. By WILLIAM H. BENNETT, F.R.C.S., Surgeon to St. George's Hospital; Lecturer on Clinical Surgery and on Anatomy in St. George's Hospital Medical School; Member of the Board of Examiners, Royal College of Surgeons of England. With Three Plates. London: Longmans, Green, and Co. 1889.—These lectures are already familiar to our readers, as they originally appeared in our columns. We are not, therefore, called upon to do more than refer to their publication in book form, and to indicate their general purport. The lectures are founded upon an analysis of a series of cases, which are arranged in two tables of males and females, in a way to indicate several important features. Mr. Bennett adopts the view, now held by many, that in a large proportion of cases varicose veins must be regarded as a primary overgrowth of veins, and not as a result of increased intravenous pressure. This view rests upon even wider grounds than Mr. Bennett here enters upon, and its general adoption will do much to promote a more rational and successful treatment of the affection. The value and safety of operation upon varicose veins are laid stress upon in our opinion not unwisely; and, in addition, many other valuable suggestions are given. It is a useful contribution on a subject of great importance to all surgeons.

Madère, Station Médicale pour Climat des Phthisies, Climat des Diathèses. Par le Dr. C. A. M. PITTA. Pp. 103. Paris: Félix Alcan. 1889. The author, who has been many years in practice in Funchal, states that while hundreds of English and German and many Russian visitors go to Madeira, it is rarely visited by French, probably from ignorance of the means of reaching it and the advantages to be derived from its mild climate. He has written this book, therefore, with a view to afford information on these points, and on the mode of life in the island and the expense involved in residence there. He comes to consider the climate likely to prove useful in all cases of incipient or chronic lung disease, but does not give any indication of the diseases, or stages of disease, for which it might be expected to prove unsuitable. In a chapter on the meteorology of Funchal he gives a considerable amount of information as to the temperature, rainfall, winds, and amount of ozone, based on the observations of twenty years, 1865–85, which may be found useful. He has also furnished a fair description of the island, with all the necessary information as to the means of reaching it and of obtaining suitable accommodation. The book will doubtless prove useful to Frenchmen who feel disposed to try Madeira as a health resort in preference to their own sunny South; but we cannot say that it affords much information which we did not already possess.

The American Armamentarium Chirurgicum. New York: George Tiemann and Co.—This is a large quarto volume of over 800 pages and containing 1414 illustrations of surgical instruments and appliances. It differs from the general run of instrument makers' catalogues in having descriptions of the anatomy of such parts as the rectum, and in containing accounts of the proper mode of using all the instruments. These descriptions are all taken at first hand or from standard works.

THE LANCET.

LONDON: SATURDAY, DECEMBER 28, 1889.

THE ANNUS MEDICUS 1889.

THE year 1889 will be memorable in domestic history as the year of the election of County Councils under the Local Government Act of the previous year carried through Parliament by Mr. RITCHIE. This is the first step in a great development of local as distinguished from central government. The medical bearings of this great development of local government are not the least of its features. It is too soon yet to judge of the wisdom or the efficiency of County Councils for securing the best ends of government. It must not be forgotten that enormous improvements have been effected in public health under a comparatively centralised system. Perhaps the most important illustration of this is the marked and continuous decline in the mortality from phthisis during the past fifty years of civil registration, a decline which has continued at an increased rate since 1880. One good thing has been done by the London County Council in the election of Mr. SHIRLEY MURPHY to the office of Medical Officer of Health. We may hope for a greater completeness of co-operation between the different parts and parishes of London, and for many other improvements in sanitary administration, from this appointment. We proceed without formal introduction to notice under a few leading heads the progress of medicine in all its branches in 1889.

Anatomy and Physiology.

Perhaps the most interesting event that has occurred in general Physiology has been the appearance of the treatise entitled "Darwinism," by ALFRED RUSSEL WALLACE, since it presents the form which Darwinism would have assumed had it been introduced to the world by the author instead of by DARWIN himself. Mr. WALLACE writes, of course, with the knowledge which he has gained from the perusal of DARWIN'S works; but it is clear from the mode in which he deals with the subject that he would have followed nearly the same lines in dealing with natural selection as did DARWIN himself. Instead, however, of basing his theory primarily on the evidence of variation in domestic animals and cultivated plants, he commences at once with the struggle for existence, which he considers to be the fundamental phenomenon on which natural selection depends, and he adduces, like DARWIN, an infinite number of instances which are either well authenticated by competent observers, or which he has himself noticed in the course of his long career as a naturalist. The whole work reads as though it had been written by DARWIN himself, and is full of the most interesting facts, all tending to demonstrate the general truth of the doctrine inculcated by this great philosopher. In the course of the year there has been a large and well-attended International Congress at Basle, where questions of the greatest scientific interest have been ably discussed by the most capable investigators. Dr. GASKELL has continued his extremely interesting work on the Nervous System, his most important paper perhaps being that which is published in the Journal of Physiology, entitled "The Relation between the Structure, Function, Distribution, and Origin of the Cranial Nerves; together with a Theory of the Origin of the Nervous System of Vertebrata." For his valuable work in connexion with the Anatomy and Physiology of the Nervous System the Council of the Royal Society have felt themselves justified in awarding him one of their gold medals—a high but well-deserved honour, which fitly crowns the recognition of his merit by the Royal Medical and Chirurgical Society, who last year awarded him the Marshall Hall prize for original investigation. The death of Dr. LEONARD WOOLDRIDGE has removed at an early age one of the most active of physiologists, and the interests of science suffer severely owing to his premature decease. The College of Surgeons is deserving of great credit for affording the younger workers, like LOCKWOOD, COLLIER, and HUNTER, the opportunity of presenting to the profession the results of their investigations in short courses of two or three lectures each, some of which are likely to become classical. Amongst the physiological works which have been issued during the year, the first place must be given to the second part of Professor FOSTER'S Text-book of Physiology. The subjects of which he treats in this part—viz., Digestion, Respiration, the Kidneys, and Nutrition—are so much enlarged as to be practically rewritten. At the same time this amplification has enabled Professor FOSTER to simplify many matters which were before obscure from the necessity of condensation. A third edition of LANDOIS and STIRLING'S excellent Physiology has also appeared, whilst Dr. MCKENDRICK has been able to complete his most useful and important Text-book on the same subject. In France one of the most noteworthy new works that has appeared is the Traité Élémentaire de Physiologie, by F. VIAULT and F. JOLYET. In the anatomical world the most interesting event of the year, next to the phenomenally small supply of subjects to the various dissecting-rooms attached to the Metropolitan Schools of Medicine, has been the formation of a committee of the Anatomical Society for the collective investigation of anatomical details, especially in regard to abnormalities. Dr. BOWLES and Dr. SYMINGTON have each contributed important papers to the same Society upon the Structure and Development of the Epiglottis. The work of 1888 in the École Pratique des Hautes Études has been published by M. RANVIER, and will be found to contain an excellent memoir by VIGNAL on the development of the elements of the Cortical Layers of the Cerebrum and Cerebellum in Man and Mammals.

Pathology.

In the brief account of pathological progress recorded in these columns last year the first place was given to Tuberculosis, as having obtained perhaps the largest share of attention. The same is true of the year that is now closing. Doubtless this is in some measure due to the impetus given to the study of this subject by the Congress held in Paris in 1888, the Transactions of which have appeared this year. Not that much more light has been thrown on the pathology of the disease or its manifestations, but rather that the views of its probable contagious nature have been more pro-

Digitized by Google

nounced, and have even led to public legal decisions. We refer particularly to the question of the identity between human and bovine tuberculosis and the liability to the transmission of the affection by the consumption of the flesh of tuberculous animals. The whole subject was very fully entered into in an inquiry that took place at Glasgow respecting the condemnation of meat from tuberculous cattle, and much of the evidence which guided the decision was based on the bacillary doctrine of the disease. The publication early in the year of Dr. CORNET'S investigations upon the dissemination of tubercular bacilli outside the body gave rise to the suggestion of measures for the disinfection of phthisical sputa &c., whilst the promulgation by the Paris Congress of a code of regulations bearing on the same subject has brought the question of infection into still further prominence. As we write, these regulations are being discussed by the Academy of Medicine, which has been asked to give them the sanction of its authority. Similar reports have been made in the United States, and everywhere there seems to be much eagerness to base prophylactic rules upon the results of pathological research. Mention should also be made of the reports upon bovine tuberculosis furnished by Professor CROOKSHANK to the Agricultural Department of the Privy Council. The somewhat allied but far rarer disease of actinomycosis has also been much studied both in animals and in man; cases have been recorded by Dr. POWELL and Mr. GODLEE, whilst some foreign observers have given instances of human pulmonary actinomycosis diagnosed during life. On this subject also much interesting detail was given by Professor CROOKSHANK in the reports referred to. The parasitic nature of malaria has been studied by CELLI and others. Drs. MACLEOD and MILLES have given considerable support to KOCH'S view of the pathogenic importance of the comma bacillus in Asiatic cholera. Although both hydrophobia and leprosy have engaged much attention, no material additions to the pathology of these diseases can be said to have been made. Dr. STERNBERG has controverted the views of Dr. DOMINGOS FREIRE upon yellow fever, but the latter has declared his inability to accept the statement that the microbe he discovered in this disease is not the pathogenic agent. Dr. STERNBERG has also furnished an able review of the etiology of croupous pneumonia, published in our pages, in which he showed the identity of the diplococcus pneumoniæ with the organism originally discovered by PASTEUR and himself in saliva. Indeed, pneumonia continues to be the subject of much bacteriological research, and the diplococcus has been found in association with many other inflammatory affections. WEICHSELBAUM has made an extended investigation into the bacterial relationships of various forms of endocarditis, and there would seem to be no diminution in the vigour with which the fascinating pursuit of bacteriology has been carried on in all centres. Cancer has been treated by Professor MARSHALL in his suggestive Bradshaw Lecture, but we still seem far off the solution of the problem of its true nature. Little has been heard, for example, of the microbic theory of cancer advanced two years ago, and so clearly disproved by Messrs. SHATTOCK and BALLANCE, although HANAU has recorded the successful implantation of cancerous growths by grafting on the rat. Some attention has been given to the subject of the transmission of infective disease from the maternal to the fœtal organism, and also to the subject of the inheritance of acquired defects. Amongst special subjects may be mentioned Fœtal Rickets studied by STILLING, KIRCHBERG, and MARCHAND; Cirrhosis by ACKERMANN; Suppuration by GRAWITZ; Pneumonia by FOA; Acromegaly by MARIE, VIRCHOW, and others; and the invaluable report upon Myxœdema issued by a Committee of the Clinical Society. Dr. TOOTH added materially to our knowledge of the pathological anatomy of chronic changes in the spinal cord in his Goulstonian Lectures. There has been a considerable addition to the literature of Pathology during the year. We have to note the appearance of the reports from the Laboratory of the Edinburgh Royal College of Physicians, the publication by Professor HAMILTON of the first volume of his exhaustive and original Text-book of Pathology, and the issue of new editions of such well-known works as Professor ZIEGLER'S Allgemeine Pathologische Anatomie, of Dr. COATS' Manual of Pathology, and of Dr. GREEN'S Morbid Anatomy, which is now edited by Mr. STANLEY BOYD. Amongst the new books in this department are the second volume of Professor KLEBS' large treatise upon General Pathology, the Guide to Practical Pathology by ISRAEL, and the Manual by Dr. NORMAN MOORE. To the New Sydenham Society we are indebted for the publication of a translation of COHNHEIM'S famous Lectures on General Pathology, and also of RAYNAUD'S Memoirs on Symmetrical Gangrene. Mr. BLAND SUTTON has published an attractive monograph on Dermoids. Of the work done by the Pathological Society in the advancement of pathological science it is needless to speak, but no one can follow the record of its proceedings without being convinced of the material aid it gives to this cause and the interest of the discussions that arise at its meetings.

Progress of Therapeutics.

Notwithstanding the numerous public gatherings of the year at which Pharmaceutical and Therapeutical progress is currently reported, some of the best work is to be found in scattered papers which have been published independently of congresses and associations. It might, indeed, be said that knowledge cannot afford to wait for public meetings, any more than it can be specially manufactured for them. An observer who feels he has something to say, hastens into print in the hope of submitting his views to the experience and criticism of a wider public. On the other hand, the work brought before public gatherings is not infrequently of a somewhat sketchy description, and hence challenges, and sometimes finds, contradiction with increasing experience. Of all the meetings of the year, perhaps that held in Paris was the most disappointing in the material set forth. Still the year has introduced many new remedies and many valuable contributions to the progress of therapeutics. Some of the new remedies, after being mentioned once or twice, seem to have speedily fallen into obscurity. The ardent accounts of early observers sink into silence which is eloquent. Pyrodine and exalgine are thus in the clouds; the former shrouded in many rumours of danger, the latter in great uncertainty as to its chemical composition. Strophanthus, however, has been attacked with great

Digitized by Google

vigour, and however little is therapeutic position is be-yond, there is no doubt that Dr. Pavay's researches upon its composition will hold a deservedly high place. This extraordinary opened slaughter-house, and a possible explanation appeared to lie in the different varieties with which the market was flooded: so soon as it seemed to bear any particular commercial value. Very early in the year the Pavian Academy of Medicine opened fire upon the use of the various chemical preparations of horse flesh, which, while it also mentioned as "calyptus colonia" although a very recent introduction, has already undoubtedly the power of the comparative disinfectants given by Dr. Lancet, the Academy declared that the "calyptus colonia" was a new name, and that it appears to be the identical remedy which has been in use for many years by Pavian doctors under a new name. Perhaps the issue

work that is going on now consists in "levelling up." And this "levelling up" is of two kinds—it affects surgeons and surgery. The success of one becomes the experience of many, and methods of examination or of treatment of one disease or organ are applied more widely to other diseases or other organs. Our columns during the year have borne ample testimony to the enterprise and the success of surgeons in all departments. There has been no new development of intracranial surgery to record, but a very good case of trephining for extra-meningeal hæmorrhage was reported in THE LANCET early in the year, one feature of interest in the case being the absence of fracture of the bone. The removal of the superior cervical ganglion of the sympathetic nerve for epilepsy is a new operation, and it has met with such a fair measure of success that a careful study of it, and its repetition in well-selected cases, seem to be called for. In the surgery of the chest some excellent results have been obtained by injecting emulsion of iodoform into the pleural cavity after evacuating the pus of empyema. The abdominal cavity has so long been the favourite field of many surgeons that it is difficult to add to their trophies. The work initiated by SENN of Milwaukee has borne some good fruit, and there is no doubt that his methods and modifications will form a very valuable addition to the surgeon's means of dealing with many varieties of intestinal obstruction, perforation, and wounds. Electric endoscopy is making way, and in some surgeons' hands the electrolytic treatment of urethral stricture seems to have given good results. In the surgery of the limbs there has not been much to call for special notice. The treatment of obstinate or incurable lesions of the soft parts by removal of portions of the bone or bones is a novel procedure that has been practised with success in Scotland. The injection of a solution of iodoform in cases of tubercular disease of bones and joints has given good results, and promises to be a useful procedure when carefully carried out. Arthrectomy has certainly gained in favour with many surgeons, and the formal excision of diseased and injured joints is becoming a less frequent operation. The treatment of old unreduced dislocations of the shoulder by direct operation has recently been described by Sir JOSEPH LISTER, and his two cases of this operation were so successful that other surgeons who have confidence in their aseptic methods of treatment will no doubt follow his example. From such brilliant illustrations of the value of the aseptic treatment of wounds, it is natural to pass to a review of the recent changes in wound treatment. A few years ago a cry was raised "*Fort mit dem Spray*," and to-day the familiar hiss is rarely heard. The most recent improvement has been in response to the cry of "Away with drainage-tubes!" And, although these admirable adjuncts to surgical dressings promise to hold their own in many cases, their field of usefulness has been greatly narrowed of late. Many surgeons rarely use them for recent wounds and in many operations, and thereby obtain a more simple, rapid, and complete healing of such wounds. This result has been obtained partly by the free use of corrosive sublimate solution for irrigation of wounds, and partly by a more careful application of equable, firm, and yet elastic, compression of wounded parts. This latter is no new method of treating wounds, and was successfully practised and eloquently advocated for many years by, among others, the late SAMPSON GAMGEE. This year has also witnessed the introduction to the profession of a new antiseptic dressing in the form of the double cyanide gauze of Sir JOSEPH LISTER. The remarkable series of experiments, giving most unlooked-for and beautiful chemical and physical results, which have led up to the production of this gauze in its latest form, will always make an interesting chapter in the history of the development of aseptic surgery and dressings. They admirably illustrate Sir JOSEPH LISTER'S caution and true scientific spirit, as well as his thorough knowledge and keen insight, although the final verdict on the gauze has yet to be pronounced.

Obstetric Medicine.

The past year has shown considerable activity in this department. To the Obstetrical Society of London the following communications have been made:—On Methods of Craniotomy, by Dr. ARCHIBALD DONALD, containing a plea for turning and perforation of the after-coming head as an operation of choice in certain cases; a Successful Porro's Operation for Contracted Pelvis, by Dr. GALABIN; a Successful Cæsarean Section for Contracted Pelvis, by Dr. CHAMPNEYS; a paper on Acute Non-septic Pulmonary Disorders, by Dr. JOHN PHILLIPS; another by Dr. HERBERT SPENCER, on the Possibility of Feeling the Placenta by Abdominal Palpation; a paper on Certain Peculiar Vaginal Lacerations, by Dr. MATTHEWS DUNCAN; Contributions to the Anatomy of the Pelvic Floor, by Dr. HERMAN; and a paper on Closure of the Ostium of the Fallopian Tube, by Mr. ALBAN DORAN. The Edinburgh Society are still largely occupied by the Anatomy of the Pelvis, as the following contributions to their Transactions show: — Note on SAEXINGER'S and WINTER'S Sections, by Dr. BARBOUR; Contribution to the Normal Anatomy of the Pelvic Floor, by Dr. SYMINGTON; the Nature and Aim of Investigations on the Structural Anatomy of the Female Pelvic Floor, by Dr. BERRY HART; On the Light which Sectional Anatomy will Throw upon the Mechanism of Labour, by Dr. BARBOUR. The Physiology of the Third Stage of Labour is discussed by Dr. HELME; Adherent Placenta and Expulsion of the Placenta before the Birth of the Child, by Dr. BERRY HART; Mitral Stenosis and Labour, by the same author; and the use of Nitrite of Amyl in Heart Disease Complicating Labour, by Dr. FRASER WRIGHT.

Ophthalmology.

In this branch of science the two most elaborate treatises that have been published in the course of the year are those of Mr. BERRY of Edinburgh and Dr. ERNEST FUCHS of Vienna, both of which have been written by men of considerable experience, and are well adapted for the use of the student working in the ophthalmic wards or for the practitioner. Mr. BERRY'S volume presents the novelty of having coloured drawings introduced into the text, which will certainly prove of much assistance to the learner. Amongst minor works are: "Errors of Refraction," by VALK, a carefully written work. Mr. J. HUTCHINSON, the son of the President of the College of Surgeons, has published a convenient manual entitled "Hints on Ophthalmic Practice for the use of Practitioners";

Digitized by Google

whilst Dr. MADDOX deserves credit for having written a small but serviceable treatise on "Clinical Use of Prisms and the Decentring of Lenses," a subject of much interest, and one which, though of great importance, has received but little attention in England. Another small work of value is by Dr. EDRIDGE-GREEN, who has pointed out the great improvements required to be made in the mode now adopted by the different railway companies for testing the colour vision of their officials, if the safety of the public is to be completely guarded. In the Ophthalmological Section of the British Medical Association, Mr. CRITCHETT discussed the subject of the Artificial Maturation of Cataract, and the same subject has been the theme of a short paper by Dr. PARISOTTI. Several writers have published notes of 100 cases of cataract extraction performed without iridectomy, the results being in many cases excellent, and in some, as in those of Dr. BULL, first-rate. The curious suggestion has been made by M. EMILE MARTIN that a suture should be used to unite the edge of the wound after the extraction of cataract, a proceeding that appears to be wholly unnecessary, and, even with the most careful antisepsis, fraught with danger to the eye. The circumstances under which such a method could be adopted are probably of the most exceptional nature. The Bowman Lecture was delivered by Professor HANSEN GRÜT of Copenhagen, before a full meeting of the Ophthalmological Society.

The Progress of Dental Surgery in 1889.

Probably no one subject has received the amount of attention, or has been discussed so fully, during the current year as the question of anæsthetics for use in dental surgery. The view so long held, that nitrous oxide was an asphyxiating agent, and thus produced narcosis, is now conclusively proved to be an error, mainly through the careful and prolonged experiments and researches of Dr. DUDLEY BUXTON, a short account of which he read at the annual meeting of the British Dental Association at Brighton. At the same meeting, Dr. FREDERICK HEWITT gave an account of 200 cases of anæsthesia with a mixture of oxygen and nitrous oxide, which he claims to be even a safer anæsthetic than nitrous oxide alone, and he gave practical demonstrations of this method. Cocaine as a local anæsthetic in dental surgery has not quite come up to the first expectations. Injected into the gum for tooth extraction, its anæsthetic action is not certain, and a number of cases of its toxic effects have been recorded, fortunately with no fatal results; but in many other dental operations, such as its application to irritable gums, it is a most valuable adjunct to the Dental Pharmacopœia. The implantation of a natural tooth into a socket drilled in the alveolus has not found general favour in this country, although it has one or two powerful advocates; and a case was shown recently by Mr. GEORGE CUNNINGHAM of a bicuspid implanted two years before, which had the appearance of having grown in its situation. The operation has lately been severely criticised in the land of its birth—America,—where some have gone so far as to implant artificial teeth with platinum wire roots. That bugbear of the dental surgeon, pyorrhœa alveolaris, or Rigg's disease, has come under the clinical observation of Mr. JONATHAN HUTCHINSON, who believes it to be a local contagious inflammation, and therefore to be attacked locally by antiseptics; but at present the results of treatment are far from encouraging, that by sulphate of copper perhaps, being the best. Of antiseptics generally, bichloride of mercury has become a special favourite, notwithstanding the great objection of its eroding effect on fine dental instruments, and peroxide of hydrogen is spoken most highly of by those who have tried it. Electricity (as supplied from a primary battery) has long been utilised to run the electric mallet for gold plugging, and is now laid under contribution for the electric mouth mirror, cautery, and dental engine. Mr. KIRBY, who has made many experiments with regard to the electric motor, has a dental engine which works well from a series of "Smee" cells; but the electric current, as supplied to houses, is looked forward to as the motor source of the future, whether supplied by high or low tension, or alternating currents. The application of gold crowns, with or without a facing of porcelain, to teeth which are broken down is gradually gaining ground, and bridge-work, or the attaching of several teeth to two or three standing teeth or roots, is a distinct advance when not abused. HOW'S method of inlaying a carious tooth with porcelain in certain cases, instead of inserting a gold filling, which is so conspicuous, has been alluded to and demonstrated by Mr. WILLIAM HERN. The British Dental Association has been continuing its warfare against illicit practitioners, and that most successfully, sweeping away many names from the Dental Register. Guy's Hospital has established a regular school for Dental Surgery and a special department for dental training, which we hear is a success.

Public Health and Sanitary Legislation.

The improved condition of the public health, as indicated by the lowered mortality-rate, which had been a marked feature of 1888, was continued into the first quarter of the present year, when the general death-rate was lower than in any corresponding quarter since the commencement of civil registration, except the first quarter of 1884. The zymotic rate was also below the mean; indeed, diphtheria was the only disease coming directly within the control of sanitary administration in which the mean was exceeded. During the second quarter of the year a similarly satisfactory general rate and zymotic rate was maintained; and it is noteworthy that during both the first and second quarters the mortality from small-pox was lower than during any corresponding period for which statistics are available. During the third quarter a rise in mortality was observed, when compared with the unprecedentedly low rate experienced in the corresponding quarter of 1888, but the general rate was still below the mean for the preceding ten years. To some extent the rise which had taken place was due to an excess of diarrhœa when compared with the extremely low rate which had obtained during the cold and wet summer of the preceding year. During the current year the rainfall for the third quarter had been below the average for the corresponding periods in seventy-four years; and the mean temperature, which was 58·9° F., was only 0·8° below that for the corresponding quarters of the previous 118 years. So also, whilst the zymotic rate, taken as a whole, was below the mean, fever somewhat exceeded the average rate in the ten preceding quarters, and the diphtheria rate considerably

Digitized by Google

exceeded that in any previous third quarter on record, a number of local epidemics of this disease having occurred. Some of these were in large towns, such as Manchester, Preston, Salford, Plymouth, and London; and this feature of the extension of diphtheria from rural to urban districts, to which we have before adverted, would seem to be becoming more and more accentuated. Foreign epidemics have formed no special danger to England during the year, and it is only just at its close that any such risk occurs. We refer to a prospect of an invasion of the epidemic of influenza, which, having apparently commenced in Russia, where it has occasioned great distress, has travelled westwards across the continent of Europe. But the epidemic has seemed to become milder as it has progressed towards the west, and probably the most that we need anticipate are discomfort and inconvenience from an affection which, apart from meteorological changes, which we hope to avoid at this season of the year, is not usually one which occasions much loss of life. One of the most important features of the year in regard to public health has been the appointment of a Royal Commission to inquire into the subject of Vaccination and of the administration of the Vaccination Acts in this country. We have already commented at length on the first report issued by the Royal Commission. It dealt exclusively with the case in favour of vaccination as a preventive of small-pox, and pending the publication of evidence on other aspects of the system of public vaccination as practised in England and Wales, we would limit ourselves to saying that, so far as it goes, the evidence tending to show that the prevention of small-pox has been due essentially to vaccination, and not to any such other improvements as have conduced to the lowering of many of the other zymotic diseases, seems to us so overwhelming that it can hardly be gainsaid. The legislation of last session included the Act for the Notification of Infectious Diseases; and although we deemed it our duty to object to the precise method by which the notification was to be carried out, we felt all along that, for the protection of the public, it was of the greatest importance that sanitary authorities should be in possession of information as to the prevalence, apart from the fatality, of infectious diseases in their midst. The public, as represented by sanitary bodies, have shown their appreciation of the Act in a manner that almost savours of impulsiveness; for whereas the adoption of the provisions of the Act is voluntary except in the metropolis, we learn that several hundred provincial authorities have already decided to carry out the system of compulsory notification for their several districts. In one sense this is a satisfactory result of a piece of legislation which was regarded as tentative only; but, on the other hand, we know that many of the sanitary authorities about to put the Act in force are without the means of isolating the cases of disease with which they will become acquainted, and we cannot but fear that, in this essential respect, their action may turn out to be premature. But if the newly acquired information as to the extent to which infectious diseases are spreading amongst the public leads to the provision of hospitals for the isolation of the first cases heard of, and so to the checking of disease in the future, a great indirect good will have been attained. Another Act was passed during the session which tends to put our general sanitary administration on a firmer and more permanent footing. We refer to "An Act to remove doubts as to the power of the Local Government Board to make Regulations respecting Cholera." Unfortunately our system for dealing with imported foreign diseases is complicated by the fact that whilst the Local Government Board has been constituted the Central Sanitary Authority for England and Wales, the quarantine functions which the Privy Council has possessed from a somewhat antiquated period still remain in the hands of the latter body; and hence whilst the Local Government Board have long since decided that it is undesirable to use quarantine for the purposes of cholera, the Privy Council had retained their power to order that ancient restriction to be put into force against that disease whenever they chose. It is quite true that they have hardly any machinery for properly putting their powers into operation; but for all that they have clung to their former functions in the matter. And, this being the case, doubt arose as to the legality of the modern and more reasonable action embodied by the Local Government Board in their Cholera Order. This doubt has now been set at rest, in favour of the Local Government Board, by the Act referred to, and it is to be hoped that this constitutes a first step towards the complete concentration of the powers for the promotion and protection of the public health in one Government department instead of leaving them scattered amongst a number of offices, which have neither the advantage of machinery for putting them in motion, nor a skilled staff to advise when and how action should be taken.

Medical Jurisprudence and Toxicology.

The year which is now closing will not have passed without its full complement of cases ranging themselves under the head of Legal Medicine. There have been perhaps fewer sensational incidents than usual. The most notorious have been those of homicidal arsenical poisoning, in which the culprits were women. FLORENCE MAYBRICK was convicted of having killed her husband by administering to him repeated doses of arsenic. The death sentence was commuted to penal servitude for life after a prolonged investigation of the medical evidence by the Home Secretary. We see no reason to alter the opinion we formed, after an exhaustive analysis of the evidence, that death resulted from arsenical poisoning, although it was a doubt on this point felt by the Home Secretary that led to the convict's reprieve. The wholesale poisoning by arsenic at Deptford by a woman named WINTERS recalls to mind a similar series of atrocities enacted in Liverpool a few years since. In each case the motive was the same—the gain of a few pounds, for which the lives of the victims were insured. It is evident that the existing law is too lax both as regards life assurance and the sale of poisons. We have recorded suicidal deaths from prussic acid on two occasions. A woman at Hammersmith committed the fatal deed impelled by jealousy at the alleged faithlessness of her lover. Had medical aid been obtained, the event might have been averted, as death did not ensue until forty minutes after the poison was swallowed. A medical practitioner took his own life by hydrocyanic acid whilst suffering from temporary insanity induced by insomnia and mental strain. There have been several instances of

Digitized by Google

poisoning from inhalation of carbonic oxide. In Wales four persons were found in a state of insensibility from breathing charcoal fumes emitted from a fire-grate. Fortunately they all recovered. The death of a gentleman in a bath led us to comment on the danger attending the use of geysers when not fitted with a ventilating pipe to carry off the products of combustion and any escaped gas. It should be generally known that a gas flame playing on a metal surface cooled by water circulating in the geyser tends to prevent full combustion of the gas, some of which may escape unburnt, whilst incomplete oxidation will account for the evolution of a dangerous quantity of carbon monoxide. At Leeds last week a coroner's jury returned a verdict of death from carbonic oxide poisoning in the case of two men who were killed, as alleged, by breathing "water-gas." M. MAGNAN has drawn attention to the subject of *chronic* cocaine poisoning. The symptoms most commonly noticed he found to be mental and sensory disturbance, illusions of sight and hearing, with neuro-muscular irritability. Criminal abortion has called for comment on several occasions. At Dundee, HENRY BURY committed the atrocious crime of killing his wife and cutting up her body with a view of getting rid of the evidence of his guilt. The "Arran murder," in which LAURIE was accused, tried, and convicted for having killed Mr. ROSE by throwing him down a precipice, aroused considerable attention and discussion both by the public and the profession. We had occasion to point to the possible errors that might be committed in estimating the probable means by which certain injuries were inflicted.

Royal College of Physicians.

The proceedings of the College of Physicians during the year have not been very eventful. The rejection of the scheme of a medical faculty empowered to grant degrees to London students has been followed by the projected reconstitution of the University of London, on the Senate of which it is proposed that the Royal Colleges should be represented. This proposal is now under consideration; but it is hardly likely to be acceded to unless the examinations conducted by the Colleges obtain due recognition at the hands of the University. Owing to this period of suspense in the agitation for a reasonable medical degree for London students, which has followed on the report of the Royal Commission, there has been no further action taken by the College. But it has not been wholly unmindful of its important educational functions, and has been engaged in negotiating with the Local Government Board for the admission of students to the Fever Asylums, a step highly necessary, and one calculated to remove the reproach that many men leave the schools and embark in practice without having had any opportunities of seeing cases of infectious disease. The College, by its action, secured some important modifications in the Lunacy Act Amendment Bill, which passed through Parliament last session. A Committee of the College reported on the subject of leprosy, and urged the renewed scientific investigation of the disease before insisting on segregation. This subject received a fresh impetus by the formation of an influential committee in memory of the heroic Father DAMIEN, and should the programme of that committee be carried out in its entirety, the wishes of the College will be fulfilled. Another matter upon which the College has expressed an opinion during the past year has been the vexed question of quarantine. It declared that, inasmuch as the period of incubation in yellow fever and cholera is uncertain, it is undesirable to enforce quarantine in those diseases; but on the ground that the incubation of small-pox was nearly fourteen days, that period would suffice for quarantine in its case. The recent regulation of the French Government respecting the admission of foreign practitioners to practise in France has naturally led to steps being taken by the College to endeavour to obtain some relief from the proposed restrictions which must press hardly on its members, and the matter is receiving consideration by a committee. On the recommendation of the Council, the College has declined to advise the extension of the curriculum to five years. Considerable progress has been made with the laboratories erected by the two Royal Colleges, and in a short time the office of director will be filled up. The foundation of such an institute certainly fills a hitherto lamentable gap in scientific London, whilst it proves that in more ways than one the conjunction of the Colleges is likely to be of great advantage to the cause of scientific medicine and surgery. The record of the proceedings of the year would be incomplete without a passing reference to the censure which the College felt bound to pass upon one who, whilst a member of the College, had in the opinion of the College transgressed the unwritten law of professional ethics. In the re-election of Sir ANDREW CLARK to the office of President, the College showed that it appreciated the zeal and devotion which he gave to its affairs during his first year of office. The resignation of Sir HENRY PITMAN of the office of Registrar, which he had held for thirty years, was received with much regret, that gentleman entering on his well-earned retirement with the good wishes of all. Dr. E. LIVEING was appointed to the vacancy thus created, whilst, in recognition of his long services, Sir HENRY PITMAN was made Emeritus Registrar. The Baly Medal was awarded to Professor HEIDENHAIN of Breslau, and the Swiney Prize to Dr. C. M. TIDY. The Harveian Oration was delivered by Dr. J. E. POLLOCK, and on the evening of the same day the Fellows dined in the College. The Milroy Lectures were given by Dr. ARLIDGE, who took for his subject Occupations and Trades in relation to Public Health. The Goulstonian Lectures were given by Dr. HOWARD TOOTH, on Secondary Degenerations of the Spinal Cord; the Lumleian by Dr. JOHN HARLEY, on Enteric Fever; and the Croonian by Dr. LAUDER BRUNTON, on the Relationship between Chemical Structure and Physiological Action. Dr. NORMAN MOORE was the Bradshaw lecturer, his subject being Visceral Growths. At a Comitia held on Jan. 9th the College unanimously approved of its President assuming the position of almoner of THE LANCET Relief Fund.

Royal College of Surgeons.

At the Royal College of Surgeons the year which has passed has not been uneventful; indeed, some of the changes which have taken place will occupy an important place in its history. The new bye-laws were officially sanctioned and came into operation before the annual election of Fellows

Digitized by Google

to vacancies on the Council held in July. By one of these bye-laws voting by means of proxy papers is permitted, and the result proved the advantages of this plan, the number of votes recorded being 600 (as against 180 last year, and an average of 270 for recent elections); of these, 462 voted by the papers sent through the post, only a few of which were invalid, and 176 recorded their votes personally. At this election Mr. HOWSE took the vacancy caused by the resignation of Sir JAMES PAGET, and Messrs. HULKE and HEATH were re-elected. Mr. JONATHAN HUTCHINSON succeeded Mr. SAVORY as President of the College, and in that capacity presided at the yearly meeting of Fellows and Members on Nov. 7th. At that meeting he departed from the customary method of procedure, and in presenting the report of the Council gave an able summary of the proceedings of that body. Various regulations with regard to the improvement of the examinations were discussed during the year. The question of making operative surgery a part of the final examination for the Membership received careful consideration, but its introduction was not deemed practicable. It was resolved, however, that a candidate should produce a certificate of having performed operations on the dead subject. He must also produce evidence "of having discharged, after having passed the second examination, the duties of a medical clinical clerk during six months, and of a surgical dresser during other six months, of which, in each case, not less than three months shall have been in the wards." Further attendance in an obstetric department is also required should he be referred at the final examination. The Council approved a recommendation of the Committee of Management that the period of professional study should be extended from four to five years, and new regulations relating to the diploma in Dental Surgery were passed; these apply to those registering as dental students on and after Jan. 1st of next year. In order that candidates for the Membership may become acquainted with the bye-laws *before* they are asked to sign them, it has been arranged that a copy be given to each candidate before admission to the examination, at such time as may be considered convenient. In the Court of Examiners in Surgery changes have occurred by the resignations of Mr. JOHN WOOD and Mr. HULKE; Messrs. MCCARTHY and EDMUND OWEN have been elected in their stead. In future years the annual election of Examiners in Elementary Anatomy, Elementary Physiology, Anatomy, Physiology, and Midwifery for the diplomas of Fellow and Member will take place at the ordinary meeting in June. The Hunterian Oration was delivered by Mr. HENRY POWER, the Morton Lecture by Professor MARSHALL, and the Bradshaw Lecture by Mr. BRYANT. Extensive alterations and improvements have been, or are about to be, made in the College premises, and an important addition to the museum department is the formation of a collection of sketches and photographs illustrating rare diseases. The library is much improved, fitted with the electric light, and at the present time is one of the best in the United Kingdom. The extension of hours, by which it is open to readers until nine o'clock in the evening, which has been tried during the last three months, will probably not be continued, as few take advantage of it after half-past seven. A memorable date in the College year was Feb. 28th, for on that day the gates of the College were closed against the Members, who had, without the consent of the President or the Council, convened a meeting to take place within the College premises; and not only were the gates closed, but police were present within the walls of the building to resist any attempt to enter. The question as to the right of Members to meet in the College without permission of the Council being *sub judice*, we shall not now further refer to it. The Council unanimously consented that the President for the time being should be *ex officio* one of the almoners of THE LANCET Relief Fund; joining in this office the President of the Royal College of Physicians and the President of the General Medical Council. In the exercise of its right to punish those guilty of infamous conduct in a professional respect &c., two Members were deprived of their diplomas. Representatives of the Council were appointed to join the Committee on the Pay, Status, and Conditions of Service of the Medical Officers of the Army and Navy; a Committee of the Board of Trade; another to consider the proposed additions to the British Pharmacopœia; and a standing committee on the Father Damien Memorial Fund. For the first time the conversazione was given by the Council of the College instead of by the President. It was a success, and the attendance was very large. The Jacksonian prize was awarded to Mr. JONATHAN HUTCHINSON, jun.

Army, Navy, and Indian Medical Services.

During the past year several important modifications have been introduced into the Army Medical Service. Early in the year a Royal Warrant was issued regulating the service of the Household Brigade. In future, and subject to the rights of the existing medical officers, the brigade surgeon and the surgeon-major of each regiment alone will be borne on the establishment; the other medical officers will be furnished by the Army Medical Staff, and will be attached to the Household troops for the term of their service at home, and subject to the regulations which apply to officers of the Medical Staff generally. An important change was made in the mode of conducting the examination of surgeons before promotion to the rank of surgeon-major, and of the latter to brigade surgeon. It is in future to be done entirely by means of printed questions, the answers to which are to be submitted to a board of experienced officers, who will report upon the competence of the officer examined. The exemption from examination of surgeons-major was also extended in some degree. In September a Royal Warrant introduced an important modification respecting the retired pay of the higher grades when the officer retires at his own request. In future, all officers above the rank of surgeon-major who retire voluntarily before they have served three years in the grade from which they retire shall only be entitled to the retired pay of the next lower rank. In March a committee was appointed to inquire into the pay, status, and conditions of service of medical officers of the Army and Navy, which, after examining a number of witnesses, reported to the Secretary of State for War in the end of July. It recommended that no change should be made in the pay of medical officers, or in the right to retire after twenty years' service, but that in case of voluntary

Digitized by Google

retirement surgeons-general and deputy surgeons-general should be required to serve two years, and brigade surgeons three years, in the rank before being entitled to the higher rate of retired pay. It may be noted that in September the War Office introduced a rule to this effect, but exacting three years' service in the rank instead of two in the case of surgeons-general and deputy surgeons-general. The Committee also recommended a change in the titles of the various grades of medical officers, and a distinct definition of their Army rank; a restriction of the term of continuous foreign service to five years; an extension to India of the advantages in pay and allowances granted to them at home and in the colonies under recent Warrants; that the commissions of medical officers entering the service should be dated from the time of entering the Medical School at Netley instead of, as at present, from that of leaving it; the abolition of the examination of surgeons-major for promotion, and a modification in that of surgeon to surgeon-major. The Committee was not by any means unanimous in these recommendations, six of the eight members having signed dissents from one or more of them. The Government has not yet given any indication of its intentions with regard to the recommendations of the Committee, except that it seems to have anticipated that which referred to service after promotion to the higher grades, but it is probable that considerable changes may be introduced into the service in the course of the coming year. In May the Naval authorities published some regulations respecting the entry of medical officers for temporary service in the department. So far as we know no steps have been taken to bring them into operation, and it seems probable that they were made with reference to any sudden call for an increase in the number of officers in case of a war. In the Indian Medical Service a rule has been recently made by which if a medical officer holding a civil appointment should decline military promotion when it comes to his turn, he must retire from the service. This has not hitherto been the rule, or at least it has not been enforced, and the promulgation of it has given rise to considerable excitement in the department.

The General Medical Council.

The General Medical Council held two meetings in 1889, each lasting five days. The first meeting began on May 28th. The President, in his opening address, announced that he had, subject to the Council's approval (which was subsequently readily granted), in common with the President of the Royal College of Physicians and the President of the Royal College of Surgeons, accepted the office and duties of almoner of THE LANCET Relief Fund. A question of precedence, he intimated, had arisen out of this co-operation of the three Presidents in a benevolent function, which up to the time of the November meeting had not yet been finally settled. Fortunately the non-settlement of it does not interfere with the hearty help and sympathy of the almoners. Among other subjects touched on by the President was the persistent frequency of indications in the Final Examination of defective preliminary education. Perhaps the most important piece of work done by the Council at its May meeting was to lay down regulations for the education and examination of candidates for diplomas in Public Health. Sir JOHN SIMON seemed pleased to think that the Council had power under Section 21 of the Medical Act, 1866, to make and enforce such regulations (though this is disputed by the Royal College of Surgeons) and to revel in the work of securing for all future time in medical officers of health a "distinctively high proficiency." At both the May and the November meetings discussions were raised with a view to lessening the expenses of the General Medical Council, which last year, chiefly owing to the cost of inspections of examinations (£1196 7*s.*), exceeded the income by £1040. Another costly item was that of printing; the compilation and printing of the General Index alone cost £595. The fees to members of Council, on the other hand, were less in 1888 by £2093 than in the previous year. The only result was an expression of opinion by the Executive Committee to the effect that the increasing delegation of work to committees might be expected so to curtail the duration of meetings as to bring the expenditure well within the income of the Council. The meetings of late have been shorter. This advantage certainly is acquired at the cost of postponing unsettled questions, as, for example, the extension of the time of medical education and the increase of clinical and practical teaching. But time itself is favourable for the right solution of such difficult problems. The Inspectors' reports on examinations and their bearing on the practical element in medical education were, on the motion of Dr. GLOVER, discussed and referred to the Education Committee, which gave in an *ad interim* report in November and promises to complete its report by May. At the second meeting, which began on Nov. 26th, the Medical Council was, as usual in November, chiefly occupied with the consideration of cases involving charges of misconduct. It is pleasant to record that the Council was more occupied in considering petitions for restoration to the Register by those whose names had been erased than in removing others. Several names were so restored. In one case, that of Mr. J. F. LEESON, for "acting as cover of, or by his presence, advice, and assistance, enabling CORNELIUS BENNETT HARNESS, an unqualified person, to carry on the business or profession of a medical electrician and to practise as if he were duly qualified," the Registrar was directed to erase the name. This decision has since been challenged in the Court of Chancery, and, this failing, in the Court of Appeal. In the latter Court two judges out of three supported the finding of the Council and the third dissented on a side issue affecting the constitution of the Council. On several motions the question of the education and registration of midwives was raised, and the Council agreed to represent to the Government that it was one which called urgently for legislation. Towards the end of the November session Sir WILLIAM TURNER, Dr. ATTHILL, Dr. CAMERON, and other members tried hard to procure some mitigation of the severity of the resolutions passed in June for the obtaining of diplomas in State Medicine by practitioners registered after January, 1890, but without further success than the giving a power, in special cases, to the Executive Committee, to allow exceptions, and that the Resolution requiring six months' practical study of the duties of out-door sanitary work under a medical officer of health of high position be not at present insisted on.

Higher Medical Education in London.

The important features in medical education in London during the past year are the publication of the Report of the Royal Commissioners on Higher Education in London and of the evidence laid before them, and the circulation of the basis of a scheme for the reconstitution of the University of London on the lines suggested by the Commissioners. The question of extending the curriculum of medical education and of filling up some of the gaps in the "practical teaching of to-day" have also attracted much attention; and, although at present postponed, must be fully considered by the General Medical Council and the various examining boards during next year. Certificates of having performed systematic operative surgery on the dead subject, in deference to the report of the inspector of surgery appointed by the General Medical Council, are now required from every candidate for the qualifications of the Conjoint Examining Board in England, and there are many complaints among anatomical teachers and students as to the insufficiency of the present supply of subjects for dissection in the London medical schools as being in part due to this recent regulation. The Royal Commissioners have unanimously rejected the petition of the Royal Colleges of Physicians and Surgeons, who asked for powers to grant degrees in Medicine and Surgery, whilst allowing that a great demand exists for medical degrees attainable in London more easily than at present, and that it is desirable to provide for that want in some proper manner. They have therefore recommended a reconstitution of the University of London, in deference to the views of the legal members of the Council, Lord SELBORNE, Sir JAMES HANNEN, and Vice Chancellor BALL; although those Commissioners who have had practical experience in education—namely, Sir W. THOMSON, Sir G. G. STOKES, and Mr. WELLDON—preferred the establishment of a new Teaching University in London, leaving it to the London University to continue to discharge its present functions. This division of opinion is distinctly unfortunate, for it has prevented the Association for promoting a Teaching University in London from making any progress since the publication of the report in May last; whilst the University of London, not without great difference of opinion in the Senate, has only now circulated a scheme for the reconstitution of the University, as a basis for conference with University and King's Colleges, the Royal Colleges of Physicians and Surgeons, the Council of Legal Education, and the Incorporated Law Society. As these latter bodies are merely asked to allow their presidents or chairmen to take seats on the new Senate, the scheme will not affect them much, and will probably be accepted by them. The teaching colleges—University and King's Colleges—are to have similar privileges; but the whole scheme concerns them much more seriously, as those colleges prayed Her Majesty to grant them a Charter to be a University in and for the London district, with power to grant degrees in the faculties of Arts, Science, and Medicine, and with power also to add other faculties. In their petition, the other medical schools in London were added to their own for the formation of a medical faculty, but they practically formed the whole body of the faculty in Arts, and the greater portion of that in Science. If, therefore, the University of London in their new scheme are in full accord with the recommendations of the Royal Commissioners, University and King's Colleges will be most seriously checked in their movement to become a Teaching University for London, for in such a case, the Commissioners recommend that the prayer of the petition of University College and King's College be not granted. These teaching colleges are strengthened in their position by the statement of Sir WILLIAM THOMSON, Sir G. G. STOKES, and Mr. WELLDON, that they "doubt the possibility of effectually combining the functions of an examining and of a teaching as well as examining University in the University of London," and this is what the new scheme confessedly attempts to do. University and King's Colleges are scarcely likely to agree to a scheme which in its definition of constituent colleges makes them of no more importance in each faculty than any institution in the metropolitan district that gives instruction on an adequate scale in that faculty, especially as a distinct position as constituent colleges is recommended by the Royal Commission, and as the recognition of their courses of study is not nearly so adequate as is laid down in their report. The exemption of students of constituent colleges from the matriculation examination under certain conditions was not passed by the Senate without being contested by an important minority of the Fellows, although both matriculation and intermediate examinations are expressly referred to by the Commissioners as being unnecessary in the case of students who have undergone regular training in constituent colleges and teaching institutions associated with the University. The whole scheme shows the difficulty of any attempt to reform the University of London, with its traditions as an open examining board and its high tests of proficiency, and to convert it into a local University, such as should be founded in the metropolis, to supply the fair wants and aspirations of a London student, who wishes to carry on his studies under the supervision of the authorities of a University, and to gain the reward which such a course of study when honestly pursued should lead to. The needs of the average medical student in London, and the question as to how he is to secure degrees on terms similar to those which obtain at every other centre of medical education in Great Britain, have evidently never troubled the members of the Senate, and the only reference to them is the illusory proviso that candidates may be excused passing the Preliminary Scientific Examination if they have passed at the Royal Colleges examinations which are, to the satisfaction of the Senate, a sufficient test of competent knowledge in the subjects of the said Preliminary Scientific Examination. Considering the character of the existing examination at the University, it is obviously impossible for the Senate to accept the Chemistry and Physics at the Conjoint Board as a sufficient test, for otherwise it would be a practical admission that their examination in Science had been unnecessarily severe from the date of its institution to the present time. The Education Committee of the General Medical Council has followed in the steps of the Committee of Management of the Conjoint Examining Board of England by recommending in a general way a five years' curriculum. "The committee report that they are

Digitized by Google

unanimous in thinking it desirable that steps should be taken by the Council to fix the period of study required to obtain a registrable qualification at five years." The discussion of this report was deferred until May next, and as it will contain the first official contribution towards the solution of the problem how to remedy the grave deficiencies in the practical education of the medical student, which were so ably pointed out by Dr. GLOVER in his address to the Council in May last, its appearance will be looked for and its recommendations studied with much interest by every student and teacher.

Medical Societies.

The zeal and energy displayed by the various Medical Societies during previous years have been more than maintained during that just passed; especially have the "clinical evenings" proved very successful. There seems to have been no difficulty in procuring good cases for exhibition, and these have been fully criticised, the friendly consultations often bringing to light new facts and opinions. Our record for the year begins with a careful account by Mr. MITCHELL BANKS of Non-strangulated Hernia, and some observations by Mr. C. H. COOPER, on Scarlatina in its relation to Cow's Milk. Then follow contributions by Mr. EVAN POWELL, Dr. W. P. HERRINGHAM, and Dr. A. E. GARROD, on Chorea; Dr. NEWMAN and Dr. FELIX SEMON, on Laryngeal Carcinoma; Mr. HERBERT ALLINGHAM, on Inguinal Colotomy; Dr. ISAMBARD OWEN, on the Geographical Distribution of Disease; Professor HUMPHRY, on Back Knee; Dr. PERCY KIDD, on Laryngeal Tuberculosis; Dr. J. E. SQUIRE, on the Prevention of Phthisis; Dr. R. G. PATTESON, on Epithelioma in the Horse; Mr. ROGER WILLIAMS, on Neoplastic Growths; Mr. WILLIAM ADAMS, on Congenital Dislocations of the Hip-joints; Mr. BLAND SUTTON, on Cutaneous Horns, and Psorospermia of Kidney; Mr. MAYO ROBSON, on Nerve-grafting and the Treatment of Transverse Fracture of Patella and Cholecystotomy; Dr. HANDFORD, on Carcinoma of the Lung; Dr. ORMEROD, on Tumour of the Brain; Mr. GOLDING-BIRD, on Tubercular Teno-synovitis; Dr. G. N. PITT, on Malignant Pemphigus; Mr. GRIFFITHS, on Hydronephrosis; Mr. RAYMOND JOHNSON, on Cancer of the Large Intestine; Mr. JONATHAN HUTCHINSON, on Some Exceptional Forms of Choroiditis; Dr. DOUGLAS POWELL, on Actinomycosis Hominis; Dr. R. CATON, on Narcolepsy; Dr. SAVILL, on Hystero-epilepsy; Dr. SAMUEL WEST, on Raynaud's Disease; Professor ANNANDALE, on Excision of Bone in order to promote the Healing of Certain Wounds or Ulcers; Mr. JESSETT, on Securing the Lingual Artery during Excision of the Tongue with Scissors, and on a Novel Method of Operating on the Intestine. Dr. A. W. FOOT reviewed the subject of Chromidrosis; Dr. SAINSBURY wrote on Meningeal Tuberculosis; Mr. W. G. SPENCER, on the Formation of Mucous Cysts in the Mouth and on Bone Disease in Goats; Mr. D'ARCY POWER, on Ossifying Sarcoma; Dr. LEONARD WYLDE, on Dermoid Cyst; Mr. LEOPOLD HUDSON, on Congenital Abnormalities of the Ileum; Dr. HUGHLINGS JACKSON and Dr. BEEVOR, on Epilepsy with Olfactory Aura; Dr. B. W. RICHARDSON, on Surgical Interference in Acute Intestinal Obstruction; Mr. MALCOLM MORRIS, on Local Eczemas; Dr. KENDAL FRANKS, on Colectomy; Dr. D. W. FINLAY, on the Diagnostic Value of Temperature in Tubercular Disease; Dr. RALFE and Mr. GODLEE, on Suppression of Urine from Impaction of Calculi in the Ureters; Dr. ANGEL MONEY, on Microcephalus and Lipomatosis Neurotica; Mr. SHEILD, on the Treatment of Ulceration of the Tongue and Mouth by Opium; Mr. LENNOX BROWNE, on Papilloma of the Larynx; Mr. J. F. BRISCOE, on Cranial Osteoporosis; Mr. WHITEHEAD, on the Treatment of Confirmed Catheter Life; Dr. SIDNEY PHILLIPS, on Arterial Murmurs; Dr. RADCLIFFE CROCKER, on Pemphigus Vegetans; Dr. WHIPHAM and Dr. DELÉPINE, on Tubercular Lupus of the Larynx; Dr. PAYNE, on Molluscum Fibrosum; Dr. BURNEY YEO, on Personal Experiences of Quinine Rash; Mr. C. B. KEETLEY with Dr. HERRINGHAM, on Primary Cancer of the Pancreas; Mr. HURRY FENWICK, on Electric Illumination of the Bladder; Professor CUNNINGHAM, Observations on Brain Growth; Dr. NORMAN MOORE, on Melanotic Sarcoma; Dr. W. STEPHENSON, on the Relation between Chlorosis and Menstruation; Dr. T. J. WALKER, on the Clinical Significance of Clay-coloured Stools; Mr. BARWELL, on Lateral Curvature of the Spine; Mr. BUTLER-SMYTHE and Mr. W. H. A. JACOBSON, on Nephro-lithotomy; Dr. EDRIDGE-GREEN, on Colour-blindness; Mr. JONATHAN HUTCHINSON, jun., on Arterial Aneurysm pressing on the Optic Commissure; Messrs. EDMUNDS and LAWFORD, on Retinal Changes in Chronic Alcoholism; Mr. BUCKSTON BROWNE, on Sources of Error in Sounding for Stone; Mr. BUTLIN, on Pre-cancerous Conditions of the Tongue; Mr. M'ARDLE, on the Treatment of Local Tuberculosis; Mr. TOBIN, on Urethral Stricture; Dr. MOTT, on Aneurysm followed by Embolism; Mr. DAVY, on Excision of the Scaphoid Bone in Confirmed Flat-foot; Mr. ARBUTHNOT LANE, on the Pathology of Lateral Spinal Curvature; Mr. KNOWSLEY THORNTON, on Abdominal Nephrectomy; Sir JOSEPH FAYRER, on Tropical Diarrhœa; Mr. J. R. LUNN, on Empyema treated by Resection of Rib; Mr. TARGETT, on Diffuse Calcification of the Liver; Mr. BOWLBY, on Bilharzia Hæmatobia; Dr. GOODHART, on Cancer of Stomach following Ulcer; Mr. SHATTOCK, on the Histology of Eburnation in Osteo-arthritis; Dr. CROOKE, on Unilateral Interstitial Nephritis; Dr. D. B. LEES and Mr. H. PAGE, on Traumatic Epilepsy; Dr. STEPHEN MACKENZIE, on the Treatment of Chronic Uræmia by Morphine; Dr. WALTER FOWLER, on Laryngeal Phthisis; Mr. O'CALLAGHAN, on the Treatment of Tubercular Peritonitis by Abdominal Section; Mr. GODLEE, on Thoracic Dermoid Cyst; Mr. W. H. BENNETT, on Spinal Nerve Section for Pain; Mr. JOHN HOLM, on Medico-Gymnastic Treatment; Dr. GREVILLE MACDONALD and Mr. CHARTERS SYMONDS, on Total Extirpation of the Larynx for Epithelioma; Dr. BRISTOWE and Dr. COPEMAN, on Paroxysmal Hæmoglobinuria; Mr. HARRISON CRIPPS, on Colotomy; Mr. H. B. ROBINSON, on Cysticercus Cellulosæ from Human Muscle; Dr. DICKINSON, on Hereditary Albuminuria; Mr. ARTHUR BENSON, on Transparent Cyst of the Iris; Mr. SIMEON SNELL, on Adenoma of the Lacrymal Gland; Mr. W. A. MORRIS, on Beri-Beri; Dr. HOPE, on Meat Inspection and the Supervision of Meat-supply; Mr. CROFT, on Plastic Operations after Burns; Mr. W. ANDERSON, on Suprapubic Cystotomy; Mr. G. H. MAKINS, on Intussusception of the Small Intes-

Digitized by Google

tine; Dr. W. NEWMAN, on Inversion of the Uterus; Mr. BATTLE, on Ectopion of the Cæcum; Dr. GAMGEE, on Actinomycosis; Mr. TREVES, on the Treatment of Scrofulous Glands; Dr. H. T. GRIFFITHS, on Floating Kidney; Laparotomy for Ruptured Tubal Gestation, by Dr. THORNLEY STOKER and Mr. SUTTON; Dr. ARNOLD SCHETELIG, on the Presence of Free Uric Acid in the Urine as a Test of the Existence of the Gouty State; Dr. HAIG, on the Influence of Phosphate of Soda on the Excretion of Uric Acid; Dr. R. L. BOWLES, on the Resuscitation of the Apparently Drowned; Dr. GRAVES, on Pernicious Anæmia; Sir DYCE DUCKWORTH and Mr. JOHN LANGTON, on Removal of a Gangrenous Vermiform Appendix; Mr. BRYANT, on Partial Obstruction of a Bronchus by a Foreign Body; Dr. BEEVOR, on Apparent Movement of Objects Associated with Giddiness; Dr. BRONNER, on Keratalgia; Dr. Collins, on Penetrating Wound of the Eyeball; Dr. P. S. ABRAHAM, on Leprosy; Dr. BALLARD, on Epidemic Diarrhœa. Papers by Mr. COLLEY on Removal of the Thyroid Gland and Mr. HEUSTON on Arthrectomy brought to an end the work for the first half of the year. In July Dr. ROCKLIFFE brought forward the subject of Monocular Suppurative Iritis; Dr. M. HANDFIELD-JONES, that of Chorea in Pregnancy. The advent of autumn brought with it the removal of the Royal Medical and Chirurgical Society to their new quarters in Hanover-square, and the admirable arrangements made by the Council rendered it probable that the alterations found necessary would be completed in time for the winter session. But the occurrence of the Dock strike so retarded the progress of the works in the Society's new home, that even at present we are unable to report the completion of the buildings. With the Medical and Chirurgical Society have migrated the Pathological, Clinical, and Obstetrical Societies, and, thanks to the assiduity of Mr. J. Y. A. MACALISTER, the resident Librarian, temporary accommodation has been provided for these during the commencement of the session. Dr. HERMAN wrote on the Changes in the Pelvic Floor which accompany the slighter degrees of prolapse; Dr. THOMAS OLIVER, on Acute Lead Poisoning; Sir ANDREW CLARK, on the Hæmoptysis of Elderly Persons; Dr. THOMAS REID, on the Pathology of Trachoma; Dr. ORD, on Glycosuria; Dr. LEES, on the Treatment of Pneumonia by the Ice-bag; Dr. F. J. SMITH, on Hypertrophic Cirrhosis of the Liver; Dr. WEST, on Diabetes Mellitus associated with Addison's Disease; Dr. TURNER, on Forced Feeding in Children; Mr. RIVINGTON, on Pott's Fracture complicated with Tetanus; Mr. BARTON, on Paroxysmal Methæmoglobinuria; Dr. EWART, on the Treatment of Pneumothorax by Aspiration; Mr. F. R. HUMPHREYS, on the Clinical Examination of the Colour of the Urine; Dr. HALE WHITE, on Symmetrical Intra-cranial Aneurysms; Mr. HASLAM, on Rupture of the Gall-bladder; Dr. DE HAVILLAND HALL, on Acute Catarrhal Laryngitis; Mr. DOYNE, on Hemianopsia; Mr. PRIESTLEY SMITH, on the Size of the Cornea in relation to Age, Sex, Refraction, and Primary Glaucoma; Dr. RASCH, on Chylous Cyst of the Mesentery; Dr. CULLINGWORTH, on Vesico-utero-vaginal Fistula; Dr. LEWERS, on Lupus of the Vulva; Dr. SIDNEY MARTIN, on Pyloric Gastric Ulcer associated with Thrill; Drs. COUTTS and GARROD, on Periosteal Nodes; Dr. S. WATSON, on a Case of Ptomaine-poisoning; Dr. ORMEROD, on Gummata of the Pons Varolii; Mr. BRUCE CLARKE, on Electrolysis in Urethral Stricture; Mr. A. E. NEVINS, on the Association of Cardiac Disease with Lesion of the Female Pelvic Organs; Mr. EDWARD ROUGHTON, on Blood Tumours of Bone; Dr. BRAXTON HICKS, on Uterine Inversion; Dr. TURNER, on Post-scarlatinal Paralysis; Dr. HADDEN, Cyst of Cerebellum; Mr. GILBERT BARLING, Cancer of Breast following Eczema of the Nipple; Dr. TATHAM THOMPSON, on the Heredity of Cataract; Mr. TWEEDY, on the Treatment of Symblepharon; Dr. HILL GRIFFITH, on Tubercle of the Iris; Dr. CAGNEY, on the Administration of Drugs by Electricity; Dr. LUFF, on the Anti-Fermentative Treatment of Infantile Diarrhœa; Sir WILLIAM MOORE, on Malaria; Mr. W. THOMSON, on the Operative Treatment of Tubercular Disease of the Knee-joint. Two debates have been undertaken during the year: that on Chronic Alcoholism at the Pathological Society was concluded, and was aptly described by Sir JAMES PAGET as a "most temperate discussion on the subject of intemperance." Recently at the Medical Society of London a debate on Aortic Aneurysm was initiated by Dr. DOUGLAS POWELL in a most able speech, and interesting contributions to it were made by Dr. BROADBENT, Dr. ORD, Dr. BRISTOWE, Dr. QUAIN, Dr. SEMON, Dr. DE HAVILLAND HALL, Dr. MITCHELL BRUCE, Dr. KINGSTON FOWLER, Dr. SEYMOUR TAYLOR, Dr. MAGUIRE, and Dr. EWART. At the last Medical meeting Dr. SANSOM read a learned paper on Mitral Stenosis in Children, and Mr. WATSON CHEYNE related a case of Successful Trephining for Cerebral Abscess following Ear Disease. We conclude this short review of the work of the societies for the year by hearty congratulations to the profession on the substantial additions to scientific knowledge which have accrued to it from this source.

Association Meetings.

The meeting of the British Medical Association at Leeds, though inconveniently late, was a success. It was presided over by Mr. WHEELHOUSE, who delivered a speech on the Practical Element in Medical Education, which has given additional strength to the demand now so general for more reality in medical education. The meeting was well attended, and, whether judged by the more formal addresses or the sectional work, will bear a creditable comparison with those of previous years. No branch of medicine seemed to be neglected, and every subject was freshly handled. It would be difficult, without being invidious, to single out particular communications, but the following may be instanced as illustrations of the high and yet useful order of the work brought before the Association. Dr. DOUGLAS POWELL, on Chronic Tubercular Disease of Serous Membranes; Dr. PAVY, on Prognosis in Cases of Albuminuria; Dr. ARMAND RUFFER, on PASTEUR'S Method in Hydrophobia; Sir WILLIAM ROBERTS, on some Practical Points in the use of Antacids in Dyspepsia and Gravel; Mr. TEALE, on Details in Surgery; Mr. JESSOP, on the Treatment of Cancer of the Rectum; Mr. HENRY MORRIS, on the Surgery of the Kidneys; Mr. MAYO ROBSON, on 200 Consecutive Abdominal Sections; Dr. MOTT, on the Pathology of Cardiac Failure; Dr. BRAXTON HICKS, on the Treatment of Placenta Prævia; Dr. BALLARD, on the Training of

Digitized by Google

Medical Officers of Health; and Dr. PARSONS, on the Control of Epidemics.

The fifty-ninth annual meeting of the British Association commenced at Newcastle-on-Tyne on Sept. 11th. Sir FREDERICK BRAMWELL was succeeded in the chair by Professor FLOWER, F.R.S., who gave an opening address on the Practical Organisation of Museums. The attendance was good. Among the communications of interest to us was one by Professor SANDERSON, in the Section of Biology, on the Nature of Life, more interesting for the expression of Dr. SANDERSON'S opinion that knowledge of the essential difference between a living and a non-living body is approachable than that it has been yet gained; and we may also note one by Sir WILLIAM TURNER, in the Anthropological Section, on Heredity. The Sanitary Congress met at Worcester on Sept. 24th under the Presidency of Mr. G. W. HASTINGS, M.P.

Hospital Mirror.

During the past year the cases which have appeared in the Mirror of Hospital Practice have been published, as heretofore, on account of some special feature of interest to the profession. Although chiefly illustrating the work done in the general departments of medicine, some have represented that of special departments, and they have come from hospitals in various parts of the world. Some are important from their rarity; others from the presence of unusual symptoms, unusual complications, or pathological changes. Others show the effect of drugs, or the experience of new methods of operating—not necessarily successful, for very often more is taught by the record of an unsuccessful than by that of a successful operation. We have resumed an old custom of making editorial comments on the cases as they have been brought forward from week to week, and this has been a marked feature of the department. In many instances, these have necessarily been limited, the case having been fully commented upon in the remarks appended to it, but when it has appeared to us that a statement as to the more recent knowledge on any subject would be of interest, we have spared no pains to bring it in a concise form before our readers. This has been favourably received, and we propose to continue the custom during the coming year. There is not space to mention all the cases which have been brought forward, but a brief review of the more interesting will be advantageous. The most important contribution to toxicology was a case of recovery after poisoning by fousel oil, a large quantity having been taken. The symptoms were severe. The patient, a man aged sixty-four, accustomed to drink freely, resumed work after drinking the poison, and four hours afterwards suddenly became unconscious. The effect on respiration was very marked, and for some time artificial respiration was required, and there was much collapse. The fumes given off from the body produced severe frontal headache, giddiness, and malaise in those in attendance. The death of Father DAMIEN, whose life-devotion to the lepers attracted so much admiration throughout the country, drew attention to cases of this disease which had been under treatment in the London hospitals, and we published two illustrative of its progress. In one, the son of European parents, the disease developed in boyhood, and proved fatal at the age of twenty-two. Pyæmia was the ultimate cause of death, having developed after tracheotomy for laryngeal obstruction; in the other, also an English boy, the disease developed in India at the age of sixteen, and proved fatal from pneumothorax secondary to tubercle of the lungs at the age of twenty-five. A case of pernicious anæmia, in which recovery followed the use of arsenic, was a good example of the successful treatment of a most serious disease; the attack was very severe, but yielded to frequent small doses of the medicine. Two cases of traumatic tetanus of unusual interest are recorded: in one, part of the second digital nerve of the foot was excised, and chloral hydrate administered internally; in the other, although chloral hydrate and bromide of potassium were employed, the greatest relief appeared to be given by the subcutaneous injection of salicylate of eserine; the symptoms in both were subacute, and recovery followed. We recorded three cases of intussusception successfully treated, one by inflation of the bowel, a second by the injection of warm water, and a third by manipulation of the affected part after abdominal section. A rare complication of acquired inguinal hernia, reduction *en bloc*, the result of the patient's violent efforts to reduce his hernia, was successfully treated by operation. A most unusual condition of varix of the veins in the mucous membrane of the stomach, leading to death as a consequence of hæmorrhage from an opening due to giving way in a thinned part, is recorded. The operation for the removal of stone from the bladder of children by crushing is described in five cases, the ages varying from two years and a half to thirteen years, and the size of the stones from 9 to 370 grains; also, vaginal lithotomy in a woman six months and a half pregnant, followed by primary union. PORRO'S operation performed in a case of extreme rachitic deformity of the pelvis was successful in saving the life of both mother and child. A curious feature was the severity of the symptoms produced by tympanitic distension of the abdomen on the third day, relieved by the passage of a long tube into the rectum. An important contribution to the literature of tubercle is afforded by a case of congenital tubercle of the face, showing as it does the occasional development of the disease in utero. Few examples of tubercle of the breast are on record in English surgical ligature, although Sir ASTLEY COOPER drew attention to the condition. In the case we published the disease was noticed six years before removal in an otherwise healthy woman of twenty-one years of age. It was localised in the axillary margin of the breast, and was continuous with diseased glands by means of a thickened band of lymphatics. Excision was practised. A case of successful trephining for coma and left-sided paralysis, due to extravasation of blood between the dura mater and the bone in consequence of injury, without fracture, was of great interest. The hæmorrhage appeared to have come from the posterior branches of the middle meningeal; the diagnosis was rendered difficult at first, as the patient had been drinking. An operation for relief of paraplegia in a case of angular curvature in the lower cervical spine, due to caries, by removal of laminæ, was thoroughly successful. A new operation for the relief of extreme flat-foot by the adaptation of specially prepared surfaces of the astragalus and scaphoid bones was fully illustrated. As examples of the removal of large tumours,

Digitized by Google

we may allude to the following: Excision of the rectus abdominis muscle with the underlying peritoneum for sarcoma, in a woman aged twenty-four; excision of the clavicle for sarcoma of six weeks' growth, in a man aged twenty-nine; removal of lympho-sarcoma of tonsil and later of cervical glands without evidence of recurrence two years later; and the removal of a similar tumour from Scarpa's triangle, when it was necessary to ligature both femoral artery and vein, also another artery of large size, the patient making a good recovery.

Special Sanitary Commission and other Reports.

Early in the year the reports, which we commenced in 1888, on the British Emigration Services seemed likely to result in some practical improvement of the sanitary condition under which the great tide of emigration flows from our shores. Shortly after the publication of our Special Report on Hull, a conference was held at Liverpool by the representatives of several philanthropic societies engaged in promoting emigration. One of our Sanitary Commissioners was specially invited to attend, and the important bodies represented showed themselves most desirous of exerting their influence to obtain the application of the sanitary reforms on which we had insisted. The conference was met by the representatives of the great Canadian companies, and the friendly relations then established will not fail to bear fruit. In respect of the separation of the sexes on board, of better accommodation for the ship surgeons, and of more ample provision for the isolation of cases of infectious diseases that may occur during the passage, there is much room for improvement. The action of the emigration societies, in supporting our report, may have some effect, and this we hope to be able to verify at no distant date. The greatest difficulty arises from the filthy habits of the Russian-Polish Jews, who are as much a nuisance in the steerage cabins as in the sweating dens which were described at great length the previous year. As forming part of the great sweating question, the condition of the chain and nailmakers at Cradley Heath and in the neighbourhood became this year the subject of our special investigation, and the reports we published resulted in the Commissioner who inquired into the matter being requested to give evidence before the House of Lords Commission on Sweating. It was then very clearly established that the women were employed at blacksmith's work. They make nails and chains of a thickness and weight altogether beyond their strength, and receive wages that do not suffice to purchase the necessary amount of food for the maintenance of health. The result is frequent false presentation in childbirth and excessive infant mortality. The sweating system and the truck system both seem in full force in this unfortunate district. The suffering due to dire poverty is accentuated by an extraordinary neglect of the most elementary sanitary precautions. Surface drainage and leaking cesspools contaminate the wells that supply the water drunk by many families, and typhoid fever was prevalent in several of the districts visited by our Commissioner. After the conclusion of the Paris Exhibition, where our Sanitary Commissioners attended many of the congresses, our campaign in favour of sanitary reform was reopened by a first report on Bread-making and Bakeries, which, appearing just at the time of the bakers' strike, attracted considerable attention. The report showed how defective is the condition of the underground bakeries in London, and that these defects are not confined to poor quarters, the worst shop visited belonging to one of the most expensive and fashionable bakers of the West-end.

Previously to the bakers' strike all London had been much exercised, morally and materially, by the dockers' strike. This remarkable labour movement evoked an amount of middle-class sympathy for labour interests which may certainly be in part attributed to the articles published in THE LANCET and reproduced by the press at large, on the prevalence of accidents among dock labourers. These accidents, due to dangers inherent to the work, but more especially to over-straining and to weakness resulting from want of food, are so general that very few dockers escape serious injury. Under these circumstances the demand for shorter hours and better pay was endorsed by the public at large; and undoubtedly these benefits, if permanently secured, will help to reduce the number of accidents that formerly so frequently occurred in the docks. On the Paris Exhibition and the International Congresses held in connexion with the Exhibition we published weekly for more than six months a series of special articles extending over a hundred columns. This work was recently summarised in an article printed both in English and French. It is therefore not necessary to go over the same ground again. We need here only recall that our correspondent dealt at great length with the sanitary improvements of Paris as demonstrated by the Exhibition, and with those sections of it most likely to interest members of the profession. He also took a very active part in, and described very fully, the International Congresses on Physical Exercise and Education, on the Housing of the Poor, on Factory Acts, &c.; the Workers' Congress, the International Congresses of Hygiene, of Forensic Medicine, of Accidents to Workmen, of Free Education, and of Climatology. The French authorities and the French press have cordially recognised our endeavours to assist in bringing about that success which has made of the International Exhibition of 1889 the greatest gathering of the sort ever held in the world's history. To still further strengthen the cause of international amity among nations, we have concluded the year by some special articles on Sanitation at Brussels, and on the increased facilities now afforded to travellers in general, and invalids in particular, who have to cross the British Channel.

THE LANCET *and the Hyderabad Commission.*

Not the least interesting event of the year is the acute challenge from India of views widely held in England as to the action of chloroform in cases where it acts fatally. This challenge was thrown down in the conclusion arrived at by a Commission appointed by the Nizam of Hyderabad, of which the leading spirit was Surgeon-Major LAWRIE, M.B., M.R.C.S., of the Bengal Medical Service. The result of the experiments, made for the most part on pariah dogs, seemed to show that death was caused by respiratory failure, and that in no case did cardiac syncope occur. We felt compelled to say that such bare statements, made, by the way, at a meeting of the Hyderabad Medical School

Digitized by Google

the Duke of CONNAUGHT presiding, could not be taken as upsetting the conclusions of an English committee and of other independent authorities. This demur called forth a further statement from Dr. LAWRIE, but yet one which we could not accept as satisfactory or complete. The result was that in a letter dated Hyderabad, Aug. 18th, Dr. LAWRIE stated that he was directed by his Highness the Nizam to offer THE LANCET, as the leading medical journal, the sum of one thousand pounds to send out a representative to repeat the experiments of the Hyderabad Chloroform Commission. We could not decline an offer showing such commendable interest in a matter of enormous human and scientific importance. We therefore proposed to Dr. LAUDER BRUNTON that he should represent us in this matter. He accepted the offer, and, as our readers know, has been deeply engaged in experiment and research on this great question under conditions which do not obtain in this country, though human life depends on a right knowledge of the subject. The Commission has been entertained at a banquet, and the Minister of the Nizam took credit to the Mohammedans for being the first originators of that experimental research which in Europe has led to such magnificent results. Dr. BRUNTON expressed just praise of the Nizam's Government for having been the first Government to appoint a Commission to investigate the action of chloroform. It would be premature to form a definite opinion of the bearing of the results arrived at by the Commission, but meantime European Governments, and especially our own, should take shame to themselves that Dr. BRUNTON should have to say that in none of the laboratories of London, Edinburgh, Leipsic, Vienna, Berlin, Amsterdam, or Paris has he found the same facilities for work as at Hyderabad. Our readers may have the satisfaction of knowing that they will be put in possession of the earliest possible information on this subject.

Benevolent Societies.

In the British Medical Benevolent Fund there are two departments — immediate grant and annuity. In the grant department, which gives amounts varying from £5 to £20, either in monthly or weekly instalments, or in one sum when the committee consider that timely assistance may obviate a second appeal, the sum of £1594 has been distributed amongst 149 applicants, a full average. These grants are only given after careful inquiry and the guarantee of a subscriber's signature, and there is no publicity, canvassing of governors, or expense attending an appeal. Annuitants are selected on their merits from those who have been accepted as worthy of grants. They must be upwards of sixty years of age, and possessed of little or no income. At present they number 65; of these, 58 receive £1 13*s.* 4*d.* monthly, and 7 medical men by the operation of a special fund have £26 a year, or 10*s.* a week. Besides these there are two DUNLAP gift annuitants of £15 each, elected under the conditions of the will of Mrs. DUNLAP. This fund may be recommended on account of the large amount of good done at very little expense, all the offices being honorary with the exception of the collector. The secretary for finance, Dr. SIDNEY PHILLIPS, will be glad to receive subscriptions, and the secretary for cases, Mr. EDWARD EAST, contributions of old clothes of any sort for redistribution. Sir JAMES PAGET has succeeded Sir GEORGE BURROWS in the Presidency. We must not fail either to observe that 1888 has seen the centenary of the Society for Relieving Widows and Orphans of Medical Men in London and its neighbourhood, which has for its president Sir JAMES PAGET, who has spared neither time nor trouble to promote its interests. The beneficiaries of the fund were voted an extra grant in honour of the centenary, and the Council were entertained to a most hospitable banquet by the President at his residence. The conditions of membership of this Society are so easy, and the advantages so great, that there is little excuse for medical men within the area leaving their families destitute. With respect to that Fund with which we are more immediately connected, we hope shortly to publish the first annual report, which will afford an indication of the benefits that have resulted from its administration.

Honours.

The honours to medical men, though we venture to say still short of the merits of the case, and inferior to those granted by most other European States, must not be passed over. The following honours were announced in connexion with the birthday of Her Majesty, and have given general satisfaction in the profession:—To be a Baronet of the United Kingdom: Sir GEORGE HORNIDGE PORTER, F.R.C.S.I., Surgeon in Ordinary to Her Majesty in Ireland. To be an Ordinary Member of the Civil Division of the First Class, or Knight Grand Cross of the Most Honourable Order of the Bath: Sir WILLIAM JENNER, Bart., K.C.B., M.D., one of the Physicians in Ordinary to Her Majesty. To be an Ordinary Member of the Civil Division of the Third Class, or Companion of the Most Honourable Order of the Bath: Dr. JAMES REID, Physician Extraordinary to Her Majesty. To be a Companion of the Most Eminent Order of the Indian Empire: Brigade-Surgeon ISIDORE BERNADOTTE LYON, Bombay Medical Establishment. To be an Ordinary Member of the Second Class, or Knight Commander of St. Michael and St. George: WILLIAM MACGREGOR, M.D., C.M.G., Administrator of the Possession of British New Guinea. To be an Ordinary Member of the Third Class, or Companion of the Most Distinguished Order of St. Michael and St. George: CHARLES GAGE BROWN, M.D., Medical Adviser to the Colonial Office. Another gracious act on the part of Her Majesty on her birthday was to appoint JAMES REID, M.D., Physician Extraordinary, to be one of the Physicians to Her Majesty. Dr. BANKS, Regius Professor of Physic in the University of Dublin, has received a K.C.B. — an honour enjoyed by the Regius Professors of Physic in Oxford and Cambridge. The distinction of the Victoria Cross was conferred on Surgeon JOHN CRIMMIN, L.K.Q.C.P.I., L.R.C.S.I., of the Bombay Medical Service, for great personal bravery in an action near Zwekaw, Eastern Karenzi, on Jan. 1st last. This rare and coveted distinction was also given to Surgeon FERDINAND SIMEON LE QUESNE for conspicuous bravery and devotion to duty displayed during the attack on the village of Tartan, Upper Burmah, by a column of the Chin Field Force. Surgeon LE QUESNE was himself severely wounded later on while attending to a wounded officer. The University of Oxford conferred its honorary degree of

Digitized by Google

D.C.L. on Dr. J. S. BILLINGS of the American Army, for his accomplishments in medical literature and other important services. The *London Gazette* of Sept. 6th contained the official account by Sir F. GRENFELL, K.C.B., of the battle of Toski and the total defeat of the dervishes. He spoke in the highest terms of Surgeon-Major HAYES and the following officers of his department:—Surgeon MORSE, 1st Column; Surgeon LEWIS, Extemporised Bearer Column; Surgeon PINCHING, Second Column. He reports that Surgeon-Major HAYES had arranged for a large number of dervish sick and wounded, and had worked night and day to alleviate their sufferings, and adds that he is a most able, active, and energetic officer. Major-General Sir GEORGE WHITE, K.C.B., V.C., late commanding the Upper Burmah force, in despatches published in the *London Gazette* of Nov. 15th, highly eulogised Surgeon IGNATIUS PURCELL DOYLE, who was subsequently made a Companion of the Distinguished Service Order. Though wounded twice on Dec. 9th, 1888, he again distinguished himself on Jan. 1st, 1889. The following officers, too, he said, had well-earned mention for service in the Chin Hills: Surgeon-Major A. B. STRAHAN, 44th Gurka Light Infantry; Surgeon F. A. ROGERS, 42nd Gurka Light Infantry; Surgeon W. H. ROBINSON, Indian Medical Service, Bengal, for specially valuable service with the Mogaung Field Force; Surgeon C. S. CRONIN, Medical Staff. Surgeon-Major AYLMER ELLIS HAYES has been gazetted Companion of the Distinguished Service Order. So far it has been left to the Royal College of Surgeons of Ireland to practically recognise the merits of Surgeon T. H. PARKE, the intrepid medical companion of the unrivalled African explorer STANLEY, by making him an Honorary Fellow of the College. The professional skill, the endurance, and the bravery of Surgeon PARKE are, however, certainly worthy of a recognition of a wider and more public character—one in harmony with the importance of the services he has rendered in connexion with one of the most remarkable enterprises recorded in the history of the world. Foreign honours have also been conferred. The Emperor of Germany conferred the Red Eagle on Dr. FELIX SEMON of St. Thomas's Hospital; the King of Greece, the Grand Cross of the Saviour on M. PASTEUR; and Dr. MAX VON PETTENKOFER, Professor of Hygiene and State Medicine of Munich, has been made Commendatore della Corona d'Italia (Knight of the Crown of Italy).

Obituary.

The obituary of the profession finds only partial record in our columns. Many a practitioner dies in the midst of his labours and is missed by the community which he served without that formal biography which we are able to give in regard to some, and which is often full of interest in the case of the quietest lives spent in country districts or amid lonely hills and moors. The medical profession is in its nature a quiet and domestic one, admitting of much "fame" that is not

> "Set off to the world, nor in broad rumour lies,
> But lives and spreads aloft, by those pure eyes,
> And perfect witness of all-judging Jove."

But the names which have appeared in our obituary and which we record below are fairly representative of all that is good in our profession and record qualities of every kind and degree—from those of busy and honoured practitioners to those of pioneers in medical thought and method, innovators in medical practice. They include lives that were as complete as lives can be, and some that were just giving promise of the brightest genius. We must leave our readers to their own reflections over this list. They will be differently affected as they read it, but none will read it without sorrow; indeed, nor yet without feeling proud of names that have so creditably represented the great calling which is still left in our hands. T. KING CHAMBERS, M.D., F.R.C.P.; G. OSBORNE HABERSHON, M.D., F.R.C.P.; WALTER COULSON, F.R.C.S.; Dr. H. A. PAGENSTECHER; Professor JOHANN WAGNER, M.D.; GEORGE DUFF, M.D. Edin.; ARTHUR ROSS, M.D.; GIUSEPPE MENEGHINI; SYDNEY HOLDER, M.D.; ALEX. J. SINCLAIR, M.D., F.R.C.P.Ed.; HUNTER JACKSON BARRON, M.D.; GEORGE JOHNSTON, M.D.; Dr. ISIDOR SOYKA; Dr. O'DWYER; WESTON PEEL DAVIS, M.D. Paris, L.R.C.P.I., &c.; WM. POWELL KEALL, M.R.C.S., L.R.C.P.Ed.; C. J. B. WILLIAMS, M.D., F.R.S., F.R.C.P.; JAMES MACLAREN, F.R.C.S.E.; JOSEPH ROGERS, M.D.; FRANZ CORNELIUS DONDERS; Dr. VON LAUER; CHAS. T. CARTER, M.R.C.S.; JOHN RUTHERFORD KIRKPATRICK, M.D.; GEORGE WOODS, F.R.C.S.; ALEX. HARVEY, M.D., L.R.C.S.Edin.; JAMES BARRON, M.R.C.S., L.S.A.; ROBERT MCDONNELL, M.D., F.R.C.S.I., F.R.S.; Surg.-Major F. A. TURTON; JAMES LATTEY, M.R.C.S., L.R.C.P.; Professor E. ALBANESE; Surgeon MARTIN GAISFORD, I.M.S.; Surgeon-General JOHN SHORTT, M.D.; ALEXANDER FAIRBROTHER, M.D. Edin.; Mr. JOHN BADCOCK; LEONARD CHARLES WOOLDRIDGE, M.D., D.Sc.; G. OWEN REES, M.D.Glas., F.R.C.P. Lond., F.R.S.; CHARLES BLAND RADCLIFFE, M.D., F.R.C.P.L.; JOHN PERCY, M.D.Edin.

Conclusion.

We must now leave the year behind us with many regrets, but with more hopes—sure that it has added largely to the efficiency and renown of medicine, and with best wishes to our readers. To the future we look confidently forward in the assurance of the sympathy and support of the profession.

Annotations.

"Ne quid nimis."

DENGUE OR INFLUENZA?

AN interesting feature of the prevailing "Russian epidemic" which has attracted some attention, especially at the hands of the Paris physicians, to whom the characters of influenza, or *la grippe*, are so familiar, is the variation its symptoms have exhibited from those ordinarily present in the disease. Thus it is asserted that catarrhal characters have been notably slight, the predominant features of the few days' fever being muscular pains, prostration, headache, and in some cases a scarlatiniform eruption. Now, it is pointed out that dengue, an affection hitherto almost confined to tropical climates, prevailed extensively in Syria last spring, has since occurred widely in Constantinople, and even been observed elsewhere in the south of Europe. This fact, added to the unusual features of the present epidemic, has given rise to the notion that perhaps it is really dengue, and not influenza, which has invaded the temperate zone and been modified by subjection to altered climatic conditions. At the Academy of Medicine on the 17th inst. M. Proust, in discussing two papers on the

Digitized by Google

Syrian outbreak of dengue, contributed by M. De Brun, declared that the present epidemic in Paris, although having some features in common with dengue, could not be regarded as being that disease, but that it is really influenza with pronounced nervous symptoms. He stated that dengue has never passed beyond the limits of 45° N. and 25° S. latitude. M. Rochard added that the characteristic eruption and articular pains of dengue were not exhibited by the sufferers from the prevailing epidemic, and M. Colin said that it resembled other epidemics of *la grippe*. M. Dujardin Beaumetz, however, thought there were several points of resemblance between the two affections, and that a hasty conclusion was to be deprecated; on the other hand, M. Brouardel held that dengue and influenza were as specifically distinct as typhoid and typhus. M. Bucquoy pointed to the analogies between the two, and seemed inclined to the view that the present epidemic is dengue modified by climatic conditions. The patients he had seen complained of muscular or articular pains, and presented redness of the palate and a scarlatiniform eruption on the chest. M. Bouchardt said that dengue is contagious, *la grippe* is not; and that the latter did not extend along the lines of commercial intercourse, but was apparently influenced by atmospheric conditions. M. Proust reasserted his opinion that the epidemic was not dengue, which at Constantinople was not modified by the cold season. He also said that the eruptions noted by M. Bucquoy had not been observed by others. At the Medical Society of the Hospitals on the 18th M. Legroux introduced the topic of the epidemic, and pointed out how it differed from classical influenza, catarrhal manifestations being exceptional, headache, ocular pain, nausea, colic, and fever chiefly marking it, and recovery following after two or three days in bed. He had seen some grave cases, and cited one of a lady in whom the pains in the head were so severe, with nausea, delirium, rapid pulse, and temperature of 102·2° F., that meningitis was feared. The symptoms disappeared in forty-eight hours under treatment by antipyrin. In children he had observed coryza or bronchitis, or more often gastro-intestinal catarrh. In every case the duration was shorter than ordinary influenza. M. Sevestre had noticed two types. In some, the minority, there were the features of ordinary influenza. Others were marked by the absence of catarrh of the respiratory passages, by intense pains in the head, eyes, and loins, and by fever. In one-third of his cases there was an eruption on the face resembling either scarlatina or measles, and recalling dengue. In terming such cases *la grippe* the usual meaning of the term was altered. The speakers concurred as to the value of antipyrin. A writer in *Le Progrès Médical* (Dec. 21st), under the heading "Grippe ou Dengue," in which the outbreak among the *employés* at the Louvre at the end of November is stated to be the starting-point of the epidemic that rapidly spread through many large establishments in Paris, refers to the descriptions given by Dr. Le Brun of the Beyrout epidemic of dengue, and suggests that both influenza and dengue are now prevailing in Paris. In particular the characters of an outbreak observed in a large scholastic institution in Paris are noted as closely approximating to the latter affection—sudden onset with frontal headache or orbital pain, difficulty in walking, pain in the limbs, &c; rarely cough, but slight tickling in the throat; many having constipation, nausea, or even vomiting. The throat was congested, tongue dry, pyrexia high (102·2° to 104°), and by the end of the first day a scarlatiniform rash, which became more like that of measles on the second day, when the fever slightly abated. The rash faded on the third or fourth day, when the patients were nearly recovered. In some cases, where the patients got up too soon, there were relapses of fever, with rigors and headache, but no fresh eruption. Desquamation was not observed in any case. In the *Gazette Médical* (Dec. 21st), Dr. de Ranse points to the discussions at the above-named Paris societies as justifying the hesitation at first expressed by the Russian physicians before concluding that the epidemic at St. Petersburg was influenza. He propounds three questions, which, shortly put, are: 1. Are influenza and dengue distinct diseases or only the same disease modified by climate? 2. May they develop simultaneously in epidemic state in the same region and combine to form a hybrid affection? 3. If entirely distinct, is the present epidemic influenza or dengue? In answering these questions, and concluding in favour of influenza, he rightly says that the exceptional occurrence of some cases showing a rash is not enough to ally it with dengue, and believes that some of the earlier recorded epidemics of influenza would show as marked an absence of pulmonary catarrh as is now presented.

AN UNKNOWN MUMMY.

MR. ERICHSEN, Mr. Wallis Budge, and the other learned men who met in the Botanical Theatre of University College on the 18th of this month to perform the ceremony of unrolling an Egyptian mummy, seem to have been a little perplexed because they could not trace out the time or manner in which this curious specimen of humanity found its way into the museum of the College. It had been in the College, Mr. Erichsen said, fifty years, so that we assume it to be the oldest resident student there, but without a history. A certain degree of obscurity also surrounded the original history of this relic; for although the mummy was declared to be of male kind, and his name seems to have been made out, his age was left in doubt, the dynasty in which he lived was not discovered, and the social rank, though rather shrewdly guessed at by Mr. Budge, was not actually defined. The mummy, after being divested of the immense length of bandages in which it had been encased, was found to be in good preservation. The skin of the body was of brownish-black colour, the face dark, and the orbits charged with eyes of glass. The heart and other viscera were found between the legs, and there was no scarabæus present, nor any ornament indicating social distinction. The inference, therefore, was that the body was that of a person of the middle class of the community to which it belonged, probably about 800 years B C. In unrolling the bandages, the operator came upon a fringed slip on which the name of the person was marked—viz., "Bek-Reneth"; on another slip was written what would read as "To Osiris"; and on a third the word corresponding to our "Year," the date being absent or lost by accidental destruction. In saying that the mummy had been in the museum of University College fifty years, Mr. Erichsen gave, incidentally, a clue to its entrance there. Between the years 1829 and 1834 there was quite a season of mummy unrolling, in which the late Mr. Thomas Pettigrew, F.R.S. and F.S.A., took the leading part. Pettigrew was a man of great learning and mark in his day. He was surgeon to the Duchess of Kent; he vaccinated the Princess Victoria, our present Queen, and enjoyed considerable repute in medical circles. But he was more than a practitioner of medicine; he was a writer of many essays of general scientific interest, a valued contributor to our own columns, and, above all, a most laborious antiquarian. In this last-named branch mummies were his hobby, and one of the first and best *jeux d'esprit* of *Mr. Punch* was the play upon a Latin proverb, in which the well-known line relating to love of money—

"Crescit amor nummi, quantum ipsa pecunia crescit"—

was cleverly turned into

"Crescit amor mummi, quantum ipse Pettigrew crescit."

Pettigrew's art in unrolling mummies became, in fact, a series of events in that line. He unrolled one at the

Digitized by Google

chambers of the late Dr. Lee of Hartwell, another at the Royal Institution, a third at the Royal College of Surgeons, and a fourth at Charing-cross Hospital. Curiously, too, he records having been present about 1834 at the unrolling of a mummy in the museum of the London University (University College), which mummy had been presented to the museum of the College by James Morrison, Esq., M.P. In this instance the body had not been embalmed according to the richest method of embalming, but sufficient attention had been paid to its preservation to display the form and features of the individual. From the hieroglyphics on and within the case in which the body was contained it appeared to have been the mummy of Kannopos or Cannopus, the son of Osiri—Paaht, and Tatiosri, or Tattiosiri or Tattosiri, Cannopus signifying strength, power, or victory. The bandages of this mummy were in good preservation, but presented nothing remarkable, with the exception of the name of the individual, which was repeated in five or six places in various ways, and giving a date of the seventeenth year, which date Pettigrew was inclined to think referred to the sovereign during whose reign the embalming took place, rather than to the age of the body itself, at the time of death. It is curious to observe, in regard to this mummy unrolled fifty-five years ago in the museum of University College, that, as in the late instance, the intestines and viscera had not been returned into the abdomen nor yet placed in jars, but were found enclosed within the enveloping bandages upon the legs and thighs. The orbits were filled, not with glass eyes, but with linen, and in one of them the transparent part of the eye was attempted to be represented. It is also to be noted that no amulet, necklace, or ornament of any kind was discovered, nor were there any marks by which the social position of the deceased could be ascertained. The body measured five feet two inches. The probability is that the mummy opened the other day might have been the gift also of Mr. Morrison to the museum, and that it might have come originally from the same place of interment, or temple, where bodies of the less affluent members of an Egyptian community had been preserved. The facts disclosed in the process of unrolling a mummy present, in striking contrast, the difference of the mode of embalming pursued by the ancient Egyptian and that carried out in modern times. Now the embalmer can conduct in minutes a preserving process which cost the Egyptian as many days, and if after his process is completed he should take pains to seal up the preserved body with all the skill possible to modern art, he might leave a human body so perfect in regard to natural form and colour that after 3000 years not a lineament need be wanting for its identification that would not have satisfied even a contemporary of the dead person. We are inclined now to experience regret that in Egyptian times the art was not advanced enough to leave the embalmed in such likeness of life. But whether it is worth the trouble in these days to revive the art, in the more perfect type of it, for the edification and satisfaction of the men and women of thirty centuries hence is a wide question. Cremation is at this moment becoming the fashion, but possibly some persons would rather be so immortalised and preserved for scientific study, like William Gilbert's flies in amber, "shining in eternal sepulchres."

RECENT OBSERVATIONS ON THE MOTOR PATH.

AT the meeting of the Royal Society on the 12th inst., Dr. Beevor and Mr. Horsley read a joint paper giving an account of their recent experiments on the brain of the bonnet monkey (Macacus sinicus). The present paper is a continuation of those presented to the Society in 1887 and 1888, containing a minute analysis of the effects produced by stimulating the "motor region" of the cortex in the same species of monkey. In the present paper similar observations have been made on the excitable fibres of the internal capsule. The animals were etherised, and the internal capsule exposed by a horizontal section through the hemisphere. By means of compasses the outline of the basal ganglia was transferred to paper ruled into millimetre squares. Each corresponding square on the cut surface was then stimulated by a minimum secondary induced current. The movements were carefully recorded. Forty-eight animals were experimented on, in eight groups, representing eight levels, reaching from the corpus striatum to the crus cerebri. In addition to mapping out accurately the position of the motor path in the capsule of these animals, Dr. Beevor and Mr. Horsley analysed the tract itself, and found that the fibres had much the same relative position as the excitable areas in the cortex. Most anteriorly are the fibres connected with movements (1) of the eyes; then follow in order those (2) of the head, (3) tongue, (4) mouth, (5) upper limb—the shoulder preceding the hand, (6) trunk, and (7) lower limb—the hip preceding the foot. Further, as shown by the authors in their previous experiments on the cortex, the fibres connected with extension are, in the case of the upper limb, placed in front of those connected with flexion, while in that of the lower limb they are situated posteriorly in the capsule. Another observation of great interest in connexion with modern theories of representation of movements in each hemisphere is that, in stimulating the internal capsule in the manner described, bilateral movements of trunk muscles were extremely rare. When the recti abdominis were exposed and the corresponding fibres stimulated in the capsule of either side, contraction of one rectus only followed. It is desirable that careful clinical observations should be made in cases of unilateral convulsions &c. in man, to see how far this arrangement obtains in the human species.

DISTRIBUTION OF HYDROPHOBIA IN ENGLAND AND WALES.

THE Registrar-General, in his Annual Report for 1888, just issued, supplies some interesting and suggestive statistics concerning the distribution of the fatal cases of hydrophobia registered in England and Wales during the twenty years 1869-88. The recorded deaths from this disease in England and Wales last year were 14, and fewer than in any year since 1868, while the aggregate number in the twenty years ending with last year was 780, equal to an annual rate of 1·50 per million living. It is pointed out in the report that the statistics of mortality from this disease were dealt with in considerable detail in the Forty-eighth Annual Report of the Registrar-General, but that the question of its geographical distribution was not there discussed. As the number of deaths from this disease are not sufficiently numerous for the calculation of trustworthy rates of mortality for the separate counties, the counties are, in the report just issued, grouped together for the purpose of showing the fatal distribution of the disease. The calculated average annual death-rates from hydrophobia in the twenty years in the groups of counties ranged from 0·32 per million in Suffolk and Norfolk, and in Cumberland and Westmoreland, to 1·59 in London and its suburbs, 2·41 in Cheshire, 2·43 in the West Riding of York, and 3·39 in Lancashire. It is noticed in the Registrar-General's Report that fatal hydrophobia appears to have two centres in this country, from which it radiates into the surrounding districts. The most fatal of these centres is the county of Lancashire, where the annual mortality in the twenty years 1869-88 averaged 3·39 per million, while in the neighbouring counties of Cheshire and the West Riding the rate was not very much lower; in

Digitized by Google

Derbyshire and Nottinghamshire lower but still high rates prevailed, while further outside this centre the rate from the disease fell below the mean rate for the whole country. The other centre of infection is London, where the rate was 1·59 per million, and higher than in any of the southern counties. From London it is suggested that the disease spreads into the extra-metropolitan portions of the counties of Middlesex, Surrey, and Kent, in which the mean rate was 1·45. The fatality in this metropolitan area is, however, less than half that which prevailed in the area of which Lancashire is the centre. The Registrar-General calls attention to the fact that the geographical distribution of hydrophobia in man corresponds very closely, as might be expected, with the distribution of rabies in animals, in support of which assertion he quotes from the last report of the Agricultural Department of the Privy Council, that there are "two groups of counties or districts in which this malady is chiefly localised, and where it may be said to be enzootic. The first comprises the counties of Chester, Lancaster, York (West Riding), Stafford, and Derby; and the second includes the Metropolis and the adjoining counties of Middlesex, Essex, Kent, Surrey, and Sussex." With regard to these centres it would undoubtedly be interesting to know, as the Registrar-General suggests, whether these two centres of rabies and hydrophobia are distinguished from the rest of the country in the number or character of the dogs that are kept therein. It ought not (although it probably is through the want of uniformity in the territorial sub-divisions used for various State purposes) to be difficult to ascertain at any rate the relative numbers of dog licences issued in the various counties of England.

THE PROGRESS OF THE INFLUENZA EPIDEMIC.

ACCOUNTS daily received from the Continent show a rapid extension of the area involved in the prevailing epidemic. Indeed, it has truly become pandemic, but it is not absolutely certain that the prevalence of influenza reported from Boston and New York is due to the same source as that which has traversed the whole of Europe within the space of two months. The march of the disease has been almost steadily from east to west, and yet it has shown a certain capriciousness in visiting certain cities in the west (e.g., Paris) before appearing in some that are situated further east. Having almost died out in St. Petersburg, it is still very prevalent at Vienna, where it shows no signs of abatement. In Berlin also it has continued to prevail, and has appeared in all parts of Germany, from Hanover in the north to Saxony in the south. The garrisons in many important centres have been especially attacked, whilst in Frankfort it was reported last Monday that there "is scarcely a house here free from it." It has appeared in Belgium at Brussels and Antwerp, and in Holland at the Hague. It has invaded Italy, cases being noted at Verona; whilst in Spain and Portugal, Barcelona, Madrid, and Lisbon have become centres of the epidemic. From Paris, the disease which appeared at the close of November, and which rapidly spread through many large institutions, schools, and places of business there, come reports of some severe cases, and some deaths (from pneumonia) have been attributed to it. President Carnot has had a bad attack. But from most centres the accounts agree generally as to the comparative mildness of the attacks.

Our Berlin correspondent writes:—"The influenza epidemic has gained much ground during the last week or ten days. Professor Senator declares that it has also assumed a somewhat severer character. In one case the symptoms were so alarming that one might have taken it at first sight for a severe case of typhus. The symptoms were deep stupor, pains in the limbs, general morbid irritability, pain in the eyeballs when pressed, and in the frontal sinus (according to Senator one of the most constant symptoms of influenza), diffuse bronchial catarrh, indicated by whistling and humming sounds in the chest, and a temperature of more than 40° centigrade. It was easy, however, to distinguish the case from one of abdominal typhus, for there were no typhus spots on the abdomen and no swelling of the spleen. Senator regards antipyrin as the best remedy, though one not to be used without caution, as it easily produces weakness of the heart. It is a striking peculiarity of this epidemic that it attacks especially people who are much out of doors. None of the patients, for instance, who were in the great Charité Hospital before the epidemic broke out have been attacked, which is the exact contrary of what happens in other epidemics. Bacteriologists are searching diligently for the influenza microbe. It is stated on good authority that about ten per cent. of the population of Berlin have been attacked, but that no deaths have occurred, and that the complications (pneumonia &c.) are not more frequent than in previous epidemics. Professor August Hirsch, a very distinguished authority on the history of diseases, finds the first recorded influenza epidemic in the year 1173, when it raged in Italy, Germany, and France. In the fourteenth century four such epidemics are on record, in the fifteenth also four, in the sixteenth and seventeenth seven each, in the eighteenth eighteen, and in the nineteenth fifty-four. This unenviable distinction of our century, however, is probably due solely to the superior recording apparatus at its disposal."

CONVICTION FOR MURDER BY ARSENIC POISONING IN IRELAND.

ON the 14th inst., at the Munster Winter Assizes held in Nenagh, the trial of Michael O'Brien for the wilful murder of John Manning by giving him arsenic was concluded before Mr. Justice Murphy. The trial lasted two entire days. The verdict was one of wilful murder, and the prisoner was sentenced to be hanged on Jan. 14th. The case was clearly made out, the facts being very simple, indicating what may be called a typical case of poisoning. The deceased was the father-in-law of the prisoner, was eighty years old, and lived on his own small farm at Mangret, near Limerick. The prisoner had been a coachman in different families, including that of Mr. Murphy, a medical practitioner, but for six months previously to Manning's death he had been in very poor circumstances, and, with his wife and family, lived with the deceased. Two years ago the prisoner effected a burial policy for £18 on Manning's life, but found considerable difficulty in paying the premium of 1*s.* per week, and paid 8*s.* of arrears on the very day of Manning's death, May 2nd. No medical man was called in until the previous evening, when the deceased was in a state of collapse and nothing could be done; he was told that the deceased suffered from cramps and vomiting. The death took place at 7 A.M., and on that same day the prisoner endeavoured to ensure his speedy burial. But the district inspector called at the house, and on hearing that the deceased had suffered from cramps and vomiting, very properly reported the death to the coroner, in spite of the prisoner's protest. An inquest was held on May 4th; a post-mortem examination was made, and the viscera were forwarded to Mr. Richard J. Moss, analytical chemist, of Dublin. That gentleman found twenty-three grains of arsenic in the contents of the stomach, six grains and a half in the small intestines, two grains and a half in the large intestines, two grains and a quarter in the liver, four-tenths of a grain in the kidneys, &c., and traces in the bladder. The prisoner had procured a quantity of arsenic from different chemists in Limerick, representing himself as

Digitized by Google

still in Mr. Murphy's employ—which was untrue,—and stating that the arsenic was wanted to kill a dog belonging to Mr. Murphy's son, which was killing the sheep—another falsehood, as the dog was a most quiet and inoffensive one. Immediately after the death of the deceased the prisoner claimed the insurance money, even before he had procured a certificate of the cause of death. The agent refused to pay him the whole amount, but advanced him £2 in cash and orders for £2 16*s.* 2*d.* for funeral requisites. There were thus the motive for the crime—a very sordid one, it is true, but one which has been unhappily too frequent of late; the sudden fatal illness; the attempt to hurry the burial; the objection to an inquest; and the discovery of sufficient arsenic to kill ten persons. There was virtually no defence at all beyond the prisoner's reiterated assertion of innocence, which his own conduct throughout disproved. In pronouncing sentence, Justice Murphy (who also tried the notorious poisoner Cross) made some very strong remarks on what he termed "that odious policy called a burial policy, which in many cases appeared to be only for the purpose of trading in death and crime." This year will be ever memorable for its many poisoning cases, and it is to be observed that the well-known poisons, arsenic, strychnine, and laudanum, still continue to be used, proving that greater restrictions upon their sale to the general public are still required.

THE NEW RESEARCH LABORATORIES.

THE arrangements connected with the fitting up of the new laboratories erected by the two Royal Colleges behind the Examination Hall in the Savoy are proceeding rapidly. It has been decided to dispose of the rooms as follows:—Lower floor: 1. Motor room, to contain a water motor and fittings for combustions, &c. 2, 3. Chemical laboratory. 4. Balance room, which will also be fitted with a dark chamber for spectroscopic examinations. Upper floor: 5. Experimental workroom. 6. Microscope room. 7. Bacteriological cultivation room. On this floor will also be the director's room. It is also decided to divide the room in the east wing on the level of the lower gallery into four small rooms—viz., a workshop, mercury room, photographic room and galvanometer room, and to place the proposed library or reading room in the west wing. Finally, a room is to be set apart for use by members of the medical profession holding a diploma from either of the Colleges—subject to the permission of the director—for the purpose of short clinical investigations. The newly-formed Laboratories Committee consists of Professor J. Marshall, Mr. J. W. Hulke, Mr. Bowlby, Sir W. Roberts, Dr. Pye-Smith, and Dr. Payne, and their first duty will be to appoint a director to the laboratories.

A SIXPENNY INFIRMARY.

UNDER the above heading we referred last week in terms of disapproval to a proposal, emanating from a member of the honorary medical staff of the Bradford Infirmary, that a charge of sixpence should be made in the out-patient department of that institution for the skilled advice of the honorary physician and surgeon, the charge to include medicines. Since the meeting of the Medico-Ethical Society of Bradford was held, at which the proposal was condemned, another and, if possible, more important meeting has been held there, all the members of the profession in the district being invited by the Medico-Ethical Society to meet and consider the proposal in question. At this meeting a resolution was carried expressing "the strongest disapproval" of any proposal to accept pecuniary payment for the services of the medical staff in the out-patient department, or for the medicines they prescribe, the services of the staff being gratuitous. The local press have taken the matter up in an excellent spirit, and the *Bradford Observer* of Saturday last devotes an able leader to its condemnation, maintaining that the attitude of the general medical practitioners in opposing it is not only justifiable but highly commendable. The spirited action of the profession in so promptly meeting and condemning this proposal is deserving of praise, and will, we hope, prove an incentive to medical practitioners in other towns to let their voice be heard in similar questions.

THE DWELLINGS OF THE POOR.

WE mentioned recently the proposals of the London County Council for the amendment of Torrens' Acts, and stated briefly their nature. The Council, as the successors to the Metropolitan Board of Works, not unnaturally look for some simpler method than now exists for clearing the metropolis of the many courts and alleys which remain, an object which cannot now be accomplished in any other way than by the application of Cross's Acts. The Council hope to attain this result mainly by enlarging the definition of "obstructive buildings" and by depriving the owner of the right to retain the site. It may be expected that all vestries and district boards will not willingly take advantage of this extension of their powers, seeing that it would cast upon them the duty of administering an Act in its effects akin to those of Cross's Acts, the expense of which now falls upon the London County Council. It is probable, however, that some attempt would be made to distinguish between the small area which could be cleared by a vestry or district board under the proposed amendments, and the large area which should be cleared under Cross's Acts by the Council. The local sanitary authorities have, moreover, their remedy in Section 5 of the Act of 1885, which gives them the right of appeal to the Secretary of State, who may determine the amount which the Council shall contribute to a local improvement of this sort, and this may serve as sufficient encouragement. Mr. Matthews expressed his sympathy with the objects of the Council, and we may anticipate that he will by an amendment of Torrens' or Cross's Acts give effect to their views. The need for further legislation is obvious, for Torrens' Acts have often been found to be unworkable where demolition is needed, and Cross's Acts are cumbersome for the removal of a small number of houses such as are to be found in a single court or alley. It is to be hoped, if the vestries and district boards should obtain the powers with which the Council wish to see them endowed, they will not hesitate to use them.

THE RECENT PRIZE FIGHT.

IF aught were wanting to stamp prize-fighting with public obloquy, it would be found in the disgraceful scenes witnessed on the 23rd inst. near Bruges. From the reports to hand it appears that the supporters of Smith, the so-called English champion, finding their man likely to be beaten by Slavin, invaded the ring and made a cowardly onslaught on the latter pugilist with knuckle-dusters and sticks. The latest exhibition of the "noble art" will perhaps be not altogether an unmixed evil, for it will surely tend to emphasise the cool brutality and hideousness of men battering each other's bodies for sordid gain, and the hollow mockery of so-called prowess and valour. Some years since Lord Esher, then Sir Baliol Brett, took occasion to favourably compare a conflict with man's natural weapons—his fists—with attacks made by the means of deadly weapons, such as knives and firearms. But then his lordship referred to a phase of combativeness totally unlike the subject of this notice. The incident then under judicial consideration was a case of manslaughter, which attended

Digitized by Google

a fight without the cold-blooded predetermination which marked the Smith-Slavin encounter. The upholders of "English fair play" must have felt a rude shock to their cherished boastings. We would fain hope that it may be long ere the national character is again sullied by such a stain as it received near Bruges on Monday last.

SCHOOL BOARD PROBLEMS.

MENTAL training and instruction are so nearly identical in their mode of action that we are apt to forget their true relation as distinct, though connected, parts of one whole. Yet for purposes of education the training is as much to be considered as the learning. It was in evident recognition of this principle that a deputation from the British Medical Association lately advised the members of the London School Board that many children were mentally or otherwise unfit for the ordinary course of study, but might be usefully taught on special lines. They contended that some children of defective brain construction would, unless their deficiency were thus particularly recognised and treated, grow up idle or vicious as a natural consequence. There is a good deal to be said for their suggestion. The Board must consider as to how far and how best it can be practically carried out. For our own part, while we entirely concur in the view that thorough efficiency in teaching requires a due recognition of individual character and capacity, we should oppose any system which aimed at less than the cultivation of every available mental quality. Cram and overpressure must of course be avoided, especially in the case of poorly fed children. At the same time, it must not be forgotten that a partially trained intellect is essentially narrow in its views, and unlikely to compete successfully or honestly with another whose every faculty has been judiciously matched against the varying possibilities of after life.

A PUBLIC MORTUARY FOR MANCHESTER.

AT an adjourned meeting of the Manchester City Council held on Wednesday, the 18th inst., a resolution was passed declaring that the condition of the building at present doing duty as a coroner's court was calculated to cause serious injury to the health of those who attended it, and asking the Town Hall Committee to endeavour to provide adequate accommodation elsewhere. A letter was read from Dr. Tatham, the medical officer of health, suggesting the provision of a public mortuary in convenient proximity to the proposed new coroner's court, and fitted up with conveniences for the holding of post-mortem examinations. Dr. Tatham felt it his duty "to impress upon the Council at the present time the desirability of putting an end to the revolting system, now unavoidably adopted in many instances, of conducting post-mortem examinations in the very homes of the deceased, and of retaining corpses for that purpose often for days together in dwellings which are frequently overcrowded by the surviving relatives." We think, under all the circumstances, that the city of Manchester would do well to carry out as speedily as possible the suggestions contained in Dr. Tatham's letter.

PARTRIDGE v. THE GENERAL MEDICAL COUNCIL.

IN the Court of Queen's Bench on Friday, the 20th inst., Mr. H. F. Partridge, Dentist, Old Brompton-road, sought to recover damages from the Medical Council for erasing his name from the Dentists' Register in June, 1886, till restored by *mandamus* in September, 1887. The plaintiff failed to show malice, and Baron Huddleston gave judgment for the defendants. Our readers will remember that the *mandamus* was granted in consequence only of a technical error of procedure on the part of the Council.

DEATH FROM CARBONIC OXIDE POISONING.

AFTER a prolonged inquiry before the Leeds Borough coroner, into the cause of death of two men named Henry Tennick and Richmond French, which occurred at the Leeds forge, the jury returned a verdict of accidental death from carbonic oxide contained in water gas, which, in their opinion, was not sufficiently odorised at the time to enable the deceased to detect its escape from a stove used for the purpose of heating the cabin occupied by them. On a future occasion we intend to discuss in detail the accident above referred to.

FOREIGN UNIVERSITY INTELLIGENCE.

Brussels.—The Professorship of Pathological Anatomy, vacant by the death of Professor Wehenkel, has been given to Professor Stiénon, who has hitherto taught the pharmacology. This subject will now be entrusted to M. Jacques, *professeur agrégé*.

Greifswald.—An offer of an Extraordinary Professorship has been sent to Dr. Hoffa of Würzburg.

Halle.—The Medical Faculty has selected the name of Dr. Küster of Berlin to be recommended as successor to the late Professor Volkmann in the chair of Surgery. Dr. F. Krause, assistant surgeon in the surgical clinic, has been promoted to the rank of Extraordinary Professor.

Munich.—Prince Carl Theodor proposes to establish an ophthalmic clinic similar to that which he organised at Tegernsee. There is available accommodation in the hospital at Schwabing.

THE death of George Gordon Robertson, M.D., Deputy Inspector-General of Hospitals, took place on the 20th inst., at Melville-street, Edinburgh. He was appointed an assistant surgeon in the army in 1834. After twenty-six years' service he retired on half-pay, with the rank of Deputy Inspector-General, having been for twenty years assistant surgeon and surgeon to the Royal Scots, and first-class surgeon from 1854 till 1888.

DR. THEODORE WILLIAMS has handed to the committee of the Hospital for Consumption and Diseases of the Chest, Brompton, a donation of 500 guineas, in memory of his father, the late Dr. C. J. B. Williams, who had been connected with the hospital from its foundation, and after whom it is proposed to name a ward.

DR. HEYMANN, Professor of Hygiene in the Carolina Institute, Stockholm, and Editor of the Swedish medical journal *Hygiea*, died suddenly during a lecture he was giving in Stockholm, from cardiac disease.

WE regret to hear that Professor Botkin, physician to the Czar, and one of the leading medical men in Russia, has just died at Mentone, at the age of fifty-eight years.

DR. JULIUS ALTHAUS has been elected an Honorary Member of the Medical Society of the County of New York.

HOSPITAL SATURDAY FUND AWARDS.—At a special meeting of the Board of Delegates of the Hospital Saturday Fund, held on the 21st inst., at the central office, 5, Mitre-court, Temple, Mr. H. N. Hamilton-Hoare, the honorary treasurer, presiding, it was decided to distribute £12,000, or £2000 more than last year, among the different hospitals, dispensaries, convalescent homes, and other charities of London and the country which supplied the Fund with letters admitting subscribers to the benefits which those institutions conferred. The main bases of the grants were efficiency, usefulness, and economy of administration.

THE MEDICAL OFFICERS OF THE MERCANTILE MARINE.

To those who have to make a sea voyage, or who are interested in friends or patients who for business, pleasure, or health have to pass many weeks on board an ocean steamer, the question of the skill and capability of the medical officer in charge is often one of great moment. Yet the general experience is that a great difference is to be found not only in different lines, but also in vessels of the same company. In one ship the passenger may be fortunate to meet with a highly qualified practitioner, voyaging for his pleasure and information; in another some medical man who has taken to the service as a last refuge, broken in health or in habits, and who has obtained his berth through the interest of some director. As an evidence of the last, we call to mind an incident that occurred not long since in one of our leading lines of steamships, in which a patient who had acquired and had just been broken of the morphia habit, was placed on board by his London physician, and strict orders given to the ship's surgeon to watch over him. Before the voyage was half over this custodian was himself found dead, having taken an overdose of the drug, to which it was discovered he was habituated. Yet to this man was entrusted the care of at least seventy first-class passengers, some of them persons of eminence, to say nothing of a large number of emigrants and the crew. The question, moreover, of filling the berth of ship's surgeon with highly qualified and efficient men has become of greater importance, since so many persons now take an ocean voyage for the sake of health, and the leading companies are little aware how much the decision is determined by the character of the ship's surgeon. But beyond attending on the sick passengers the medical officer has other important duties to perform—viz., attending to the sanitation of the ship, under the instructions of the Board of Trade. Here, however, the present unsatisfactory arrangement with regard to the appointment of the ship's surgeon comes prominently forward. Should he in the course of his duty report any breach of the orders of the Board of Trade, say, for instance, the encroachment on the cubic space of the hospital quarters by stowing luggage there, he runs the risk of being dismissed his ship, and a black mark is set against his name, which renders it impossible for him to obtain employment in other companies. Such a fate seems to have befallen Mr. Leet, F.R.C.S., whose pamphlet, "The Ship's Surgeon of To-day," throws a lurid light on the discomforts and petty insolence a surgeon who attempts to do his duty by his employers, the passengers, and the crew, is exposed to from the officer in command, unless he is content to close his eyes to all abuses. No wonder that few men remain long in such a service, and as soon as the novelty wears off, or they have acquired a little money, seek other employment. And yet under proper management no service would seem more attractive: comfortable quarters, a liberal table, fair pay, the opportunity of forming many valuable friendships, and making a start in life, ought to attract some of the best of our younger men; and no doubt it would be so if they felt sure of their position.

MEDICAL TRIALS.

COURT OF APPEAL.

Leeson v. General Council of Medical Education and Registration.

JUDGMENT was delivered at the Court of Appeal on Saturday last in the appeal by Mr. Leeson from a decision of Mr. Justice North, who refused to restrain the defendant Council from removing the plaintiff's name from the Register of General Practitioners until the trial of the action, and from publishing resolutions passed by them on Nov. 28th, 1889, to the effect that he had been guilty of infamous conduct in a professional respect, or directing their registrar to erase his name.

The hearing of the arguments occupied the attention of the Court of Appeal for two days, and judgment, which had been reserved, was now pronounced.

Lord Justice COTTON reviewed the history of the case at some length, and continued:—It was said during the arguments that the Medical Council were not justified in exercising the powers given them by Section 29 of the Medical Act, 1858, and there was a good deal of verbal criticism conferred upon us in support of that contention. It was said that Mr. Harness was not acting as a duly qualified medical man, that the charge did not say so, and that Mr. Leeson only assisted Mr. Harness as if he were a medical electrician. I cannot read it in that way We know what a duly qualified medical man is. A person is duly qualified if he is on the Register, and he gets the benefit of the Act, as far as the privileges are concerned, of those who are on the Register, the Register setting forth the qualifications of those who can be put upon it. I have no doubt that the charge as stated was such as to justify the Medical Council in arriving at the decision that Mr. Leeson had been guilty of infamous conduct in a professional respect. That, in my opinion, is the true construction of the charge made against him. When it was found that he had been guilty of the acts charged against him, then there was a direction to erase his name from the Register. There has been a good deal of discussion as to what actually took place, and we have had the evidence given before the Medical Council brought before us. In my opinion it would be wrong to consider whether the Medical Council arrived at a right conclusion upon the evidence that was brought before them. That is not for us to say. The Medical Council cannot take evidence upon oath; they cannot take evidence in the same manner that we as lawyers can take it. They have statements made before them both in support of a complaint made, and on the other side by the medical man against whom the complaint is made; and if it is once established that the complaint made before them does involve matters in respect of which they can exercise the jurisdiction given by Section 29, then we ought not to consider whether the Council has or has not arrived at a right decision. If those who appeal to us say that the Council have acted corruptly, and have not proved that by showing that there was no statement made before them on which they could arrive at the conclusion at which they did arrive, then I think we ought to consider whether there was such evidence to lead us to the conclusion that they had not acted honestly on the charge brought before them. In my opinion there is no such evidence, and although there were some statements to the effect that there was prejudice against Mr. Leeson, that was not pressed upon us by counsel nor supported by anything brought before us. Mr. Leeson seems to have had the most perfect consideration given to his case by the General Council. He was present at the inquiry, he was represented by his solicitor, and he brought his own witnesses to make statements in support of his contention that he had not been guilty of infamous conduct in a professional respect. Everything was most fully heard and considered, and then the Council arrived at a conclusion. In my opinion, we cannot consider whether the Council were right or wrong in the conclusion at which they arrived. If the Council acted honestly, gave Mr. Leeson every opportunity of being heard, and fairly conducted the inquiry in question, then, according to my view, we ought not to enter into the question, because if we once do that we assume to judge whether, in our opinion, they came to a right conclusion upon the statements before them. In my opinion, the first ground that was taken in support of this application fails. I think there were grounds which would justify the Council in coming to the conclusion at which they arrived under Section 29, and there is no reason for saying that the proceedings were improperly conducted by the Medical Council. Then there was another point raised as to which there is a little more doubt. It was suggested as a second point that this order made by the Council must be considered as bad, as having been made by a non-competent tribunal, and it is said that the Medical Council was in such a position and so constituted on this occasion that any order made by them was a wrong one. It turns out that the complaint was made against Mr. Leeson by the Medical Defence Union, and that two of the members of the Council who were present when the case of Mr. Leeson was considered were members of and subscribers to the Medical Defence Union, and it was said that, that being so, they must be considered as prosecutors, and that therefore any decision arrived at by the Medical Council when these

Digitized by Google

two subscribers to the Medical Defence Union were present, and who were not competent to act, was a wrong one. To my mind, it is clear that the Medical Council, in respect to the complaint against Mr. Leeson, were acting judicially; they had to decide judicially whether a complaint against Mr. Leeson was well founded, and then, if they found it was well founded, to make an order which would be of great importance to him, and deprive him of the right of being upon the Register. One has to consider this: were either of these two gentlemen to be considered as prosecutors or complainants in this case? We must look a little at what the Medical Defence Union is in order to decide this question. This Union was a company, limited by guarantee under the Act of 1862, and one of its objects was to support and protect the character and interests of medical practitioners practising in the United Kingdom, and to promote honourable practice and to suppress or to prosecute unauthorised practitioners; further, to defend members of the Union in cases where proceedings are brought against them involving professional principle. So that it was formed not only for the purpose of prosecuting, but also for the purpose of defending those of its members against whom charges were brought. Then let us look at what the Articles of Association are. [His lordship having examined at some length the articles and objects of the Medical Defence Union, proceeded to say:] I do not consider that the Medical Council can be considered as prosecutors in a case of this kind. It must be remembered that it is only the Council of the Defence Union that has power to bring complaints of this nature before the General Council. The two gentlemen referred to were not members of the Defence Union Council, and they could not, as has been alleged, have exercised any control as to the manner in which the complaint was brought forward. In my opinion, therefore, this objection, which is a serious one, cannot prevail, and we ought to hold that Mr. Justice North was right in refusing to grant the injunction and the order asked for.

Lord Justice BOWEN, in the course of his judgment, said: As to the first point raised by the appeal, I should say very little in addition to what the Lord Justice has already stated. With respect to the charge of being guilty of infamous conduct in some professional respect, the particulars brought should be particulars of conduct which are capable of being viewed by honest persons as conduct which is infamous, and that is all that is required to be done. When we have seen that these conditions have been fulfilled, the functions of a Court of Law are at an end. It appears to me that we have no power whatever to review the evidence any more than we have the power to say whether the tribunal came to the right conclusion in this matter. If it could be shown that nothing was brought before the tribunal which would warrant the inference that infamous conduct was established, that might go to show that the inquiry had not been a proper one; but if there is nothing to show that, the decision which has been arrived at, it is plain, must be left untouched by the Courts of Law. It appears to me for these reasons that the view which Lord Justice Cotton has expressed is a sound one, and I entirely adhere to it. Next comes the question whether or not the tribunal which adjudicated with respect to the appellant's conduct was competent, or whether, in respect of two of its members, it was rendered incompetent by the fact that they had taken part in the decision arrived at as accusers. The fact is established that those interested in a decision cannot act as judges. I think it is to be regretted in the present case that when those two gentlemen found that a society to which they were subscribers, and of which they were members, was bringing a charge against a gentleman who was before the Council, they did not at once retire from the Council. I think that is much to be regretted, because justice, like Cæsar's wife, ought to be above suspicion. I trust that in future the Medical Council will think it reasonable to advise that those who sit upon these cases should cease to occupy the position of subscribers to the society. I think that, although they were members of the corporation whose Council brought this complaint before the Medical Council, they did not themselves take any part, and could not, in fact, take any part in the prosecution, and the prosecution was not conducted by the Council as their agents. The Council was supreme in the matter, and I think they stand cleared of all suspicion. For these reasons, I think that, as a matter of substance and of fact, these gentlemen were not accusers.

Lord Justice FRY, in the course of his judgment, said:—I cannot say that these gentlemen were not acting judicially. This must be held to be a judicial proceeding, because the result was to deprive Mr. Leeson of all rights that were vested in him. It is a matter of public importance that judicial proceedings should not only be free from actual bias and prejudice, but that they should be free from suspicion of bias and prejudice, and I do not think that subscribers to an association for the purpose of carrying on prosecutions can be said to be free from bias in prosecutions instituted by that association. If the matter, therefore, had rested with me, I should have held that the decision of the Council in this case was invalid, and that it was not competent to decide, and in so doing I think I should best have maintained the dignity, honour, and influence of the Council.

The appeal was therefore dismissed with costs.

Mr. RIGBY: As it is possible, my lords, that these proceedings may be carried further, do your lordships think that Mr. Leeson's name should be removed from the Register in the meantime?

Lord Justice COTTON: Yes; if the House of Lords comes to a different conclusion they can order the name to be restored.

Lord Justice BOWEN: We have no power, according to our judgment, to interfere in the matter. If you can quote to us any cases to show us that we have such power we shall be pleased to hear you.

Mr. RIGBY: If your lordships please.

QUEEN'S BENCH.

Partridge v. *the General Council of Medical Education and Registration of the United Kingdom.*

In this action the plaintiff sued the defendants, who are a quasi-judicial body taking their powers under the Medical Act (21 and 22 Vic., chap. 90), to recover damages, alleging that they had wrongfully and maliciously caused his name to be taken off the Register in June, 1886, and to remain off until ordered by writ of *mandamus* to reinstate it in September, 1887, and that during that period a number of his customers had refused to pay their accounts on the ground that under the Dentists Act, 1878 (41 and 42 Vict., c. 33), the plaintiff's name not being upon the Register, he could not at law recover his fees. The defence was in substance that the defendants, as a judicial body, had had certain matters connected with the plaintiff's professional conduct brought before them to decide, and that although the Court of Appeal had decided that their decision had been wrong, yet it was arrived at *bonâ fide* and without malice, and that therefore they were not liable in damages to the plaintiff for their mistake in exercising their discretion.

Mr. Waddy, Q.C., and Mr. Lyon were for the plaintiff; and Mr. R. T. Reid, Q.C., and Mr. Muir Mackenzie appeared for the defendants.

Mr. WADDY opened the case, and called the plaintiff, Mr. H. F. Partridge, who said he practised as a dentist at Sussex House, Sussex-place, Old Brompton-road, and had done so for twenty years. In 1878 the Dentists Act was passed compelling registration, and so he wished to become a Licentiate in Dental Surgery of the Royal College of Surgeons in Ireland. Witness went to Dublin, and passed the required examinations, and received a diploma, at the same time signing a declaration that while he held it he would not advertise in order to benefit his practice as a dentist, under the penalty of having the diploma cancelled. In February, 1882, he had gone to bed quite well in health, and awoke the next morning totally blind, and he had been so ever since. In order to obtain a living he had formed the South Kensington Ladies' Dental Institute. He had, in fact, advertised that institution. He had found it necessary to do so. He had received a copy of the resolution of the Council for Ireland in July, 1885, and a notification that they had again had under their consideration the fact of his advertising his institution, and that his diploma was cancelled. On July 11th, witness replied to that. On June 8th, 1886, he received a letter from the General Medical Council of Education in England informing him that a meeting of that Council, "after due and careful consideration, had decided that his name should be removed from the Register." Witness applied to the Court thereupon for a *mandamus* questioning that decision, and in the result the Court of Appeal ordered his name to be restored, and

Digitized by Google

it was, in September, 1887. During the time that his name was off the Register, he had been unable to sue for or recover any fees. During that time a number of his patients refused to pay him his fees. His out-of-pocket expenses over the whole matter, including his solicitor's costs, had been £36 odd.

Cross-examined by Mr. R. T. REID, Q.C.: The institution was wholly his own business, and all its profits his. From 1882 until now witness had constantly and largely advertised, and had advertised himself as an "L.D.S.," as described in the certificate to his diploma. He meant by that to describe himself as connected with the Irish Royal College of Surgeons. He was aware that by his diploma he had undertaken not to advertise. In 1883 the Dublin College complained of his doing so, and in effect he had promised not to do so any longer. Nevertheless he continued to so advertise. He thought that he had a right to use the title of L.D.S. after his diploma had been cancelled. Since he had been struck off the Register he had still advertised as L.D.S. He could not help himself. He did put L.D.S. on his "plate," but with the word "late" before the L.D.S.

Mr. Baron HUDDLESTON: When was it you put the word "late" before the L.D.S.?

Witness: Oh, a few weeks ago.

Cross-examination continued.—During the period you were off the Register was it not a fact that your income had increased?—Yes, that is so, but I ascribe it to the fact that I largely advertised during that period.

Mr. WALTER OLDHAM said he was the plaintiff's secretary since June, 1886. There were only one or two cases where refusals to pay accounts were based on the fact that the plaintiff's name was off the Register.

Cross-examined.—The plaintiff's income increased during the time his name was off the Register.

Mr. R. T. REID then said that as there was no evidence of malice here, this action could not be maintained.

Mr. WADDY, for the plaintiff, argued that the defendants had gone entirely beyond the powers given them by the Legislature, and were therefore liable in damages, there being in fact legal or constructive malice.

Mr. Baron HUDDLESTON said he might say at once that he was prepared to decide that this action would not lie unless malice were proved, and he would therefore suggest that the jury should be discharged and it be left for his decision, in which event either party could go direct to the Court of Appeal.

Mr. WADDY said his client wished the matter to go to the jury.

Mr. Baron HUDDLESTON: But I will not permit it. I have told you I am going to decide the matter at once.

Mr. WADDY: Then I can say no more, my lord.

Mr. Baron HUDDLESTON then gave judgment for the defendants, holding that there was no evidence of malice on the part of the defendants, and that therefore the action did not lie. In reviewing the facts, the learned Baron observed that the defendants, when the matter of the plaintiff's conduct in respect of the violation of his agreement not to advertise was brought to their notice, had taken his name off the Register, and subsequently, by order of the Court of Appeal, they had had to reinstate it. But for this were the defendants liable to an action? He did not think it required authority to establish that where persons in a quasi-judicial capacity exercised their discretion wrongly no action could be maintained against them for such a decision unless it could be shown that they arrived at their decision maliciously. Here there was no evidence at all of malice, and the plaintiff must therefore be non-suited and judgment entered for the defendants.

PRESENTATIONS.—Dr. Crooke, physician to out-patients of Queen's Hospital, and late Pathologist to the General Hospital, Birmingham, was presented last week by the students connected with the Birmingham Medical School with an illuminated address and a collection of medical and scientific works, in recognition of his valuable services rendered to them.—On Saturday, Dec. 21st, the Rev. J. B. Medey, Mr. Gunning, and Mr. Bray presented Dr. Evans of Beckington, near Bath, with a handsomely illuminated address signed by fifty-eight residents of the parishes of Orchardleigh, and Lullington with a purse of sovereigns, as a recognition of his work among the sick during a recent epidemic of typhoid fever in those parishes.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

PORTS OF MEDICAL OFFICERS OF HEALTH.

West Sussex.—This important combination of sanitary districts has now for fifteen years been under the medical supervision of Dr. Charles Kelly, and perusal of his several annual reports shows that if progress has in some localities been slower than might have been hoped for, yet it has been of a sort that can only tend to the improvement of public health. Much the same may be said for the report on last year's work in the eleven districts under consideration. New and efficient bye-laws have in several places been put in force; excellent regulations for the connexion of drains with the public sewers have been adopted in the Horsham rural district; a system of drainage has been carried out in West Tarring village; and a beginning of good work as to the housing of the poorer classes in Worthing has been set on foot. But some important sanitary defects still remain to be dealt with, and amongst these Dr. Kelly strongly urges the case of the drainage of Midhurst, to which attention has been called before. The area of this combined district is about 524 square miles, with a population of 106,600 persons. The birth-rate has shown a tendency to decrease. Between 1879 and 1882 it was over 30 per 1000; during the last two years it has been only about 26. The death-rate, corrected so as to exclude visitors, was last year 13·3 per 1000, the variations being between 20 3 for Arundel and 8·0 for West Worthing. Speaking of the district as a whole, the general death-rate has steadily diminished during the past ten years; and it is impossible to dissociate this important result from the improvement in sanitary administration which has been in progress. This is significantly shown in the zymotic rate of 1·2 per 1000. For 1879–88 it was 1·45, or about one-half of that for England and Wales as a whole. The infectious diseases heading the list are whooping-cough, diarrhœa, and diphtheria, which are only followed by scarlet fever, measles, &c., thus reversing the order for the country generally in so far as diphtheria is concerned. Indeed, the increase as regards this disease is one to cause some anxiety, and we may feel confident that the study of the obscure conditions under which the poison of diphtheria is steadily acclimatising itself in our midst is one that is engaging attention in the West Sussex combination.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5493 births and 4304 deaths were registered during the week ending Dec. 21st. The annual rate of mortality in these towns, which had increased in the preceding four weeks from 18·2 to 23·1, further rose last week to 23·5. During the first twelve weeks of the current quarter the death-rate in these towns averaged 19·2 per 1000, and was 2·0 below the mean rate in the corresponding periods of the ten years 1879–88. The lowest rates in these towns last week were 14·1 in Brighton, 14·8 in Birkenhead, 17·0 in Leicester, and 18·9 in Nottingham. The rates in the other towns ranged upwards to 30·3 in Wolverhampton, 32·1 in Manchester, 33·2 in Bolton, and 33·6 in Blackburn. The deaths referred to the principal zymotic diseases, which had been 383 and 378 in the preceding two weeks, rose last week to 413; they included 128 from whooping-cough, 73 from measles, 73 from scarlet fever, 52 from "fever" (principally enteric), 52 from diphtheria, 35 from diarrhœa, and not one from small-pox. These zymotic diseases caused the lowest death-rates during the week in Cardiff, Huddersfield, and Halifax; and the highest rates in Salford, Wolverhampton, and Plymouth. The greatest mortality from whooping-cough occurred in Bolton, Leeds, Salford, Wolverhampton, and Bristol; from measles in Birmingham, Newcastle-upon-Tyne, and Bradford; from scarlet fever in Liverpool and Plymouth; and from "fever" in Sunderland and Wolverhampton. The 52 deaths from diphtheria in the twenty-eight towns included 27 in London, 5 in Manchester, 3 in Salford, 3 in Sheffield, 3 in Portsmouth, 2 in Plymouth, 2 in Birmingham, and 2 in Newcastle-upon

Digitized by Google

Tyne. No death from small-pox was registered in any of the twenty-eight great towns. No case of this disease was under treatment at the end of the week in any of the Metropolitan Asylum Hospitals, and only 2 in the Highgate Small-pox Hospital. The number of scarlet-fever patients in the Metropolitan Asylum and London Fever Hospitals at the end of the week was 1594, while in the preceding twenty-five weeks the numbers had steadily increased from 559 to 1667; 115 cases were admitted to these hospitals during the week, against 154 and 144 in the preceding two weeks. The deaths referred to diseases of the respiratory organs, which had increased in the preceding eight weeks from 281 to 552, declined again last week to 518, but exceeded the corrected average by 16. The causes of 83, or 1·9 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Newcastle-upon-Tyne, Nottingham, Oldham, Portsmouth, and in six other smaller towns; the largest proportions of uncertified deaths were registered in Liverpool, Cardiff, and Halifax.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 23·9 and 23·6 per 1000 in the preceding two weeks, rose to 26·1 in the week ending Dec. 21st; this rate exceeded by 2·6 that which prevailed during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 12·0 and 12·3 in Greenock and Paisley to 26·1 in Edinburgh, 26·4 in Dundee, and 29·9 in Glasgow. The 667 deaths in the eight towns showed an increase of 63 upon the number in the previous week, and included 27 which were referred to whooping-cough, 26 to measles, 12 to scarlet fever, 9 to diarrhœa, 8 to diphtheria, 6 to "fever," and not one to small-pox; in all, 88 deaths resulted from these principal zymotic diseases, against 67 and 85 in the preceding two weeks. These 88 deaths were equal to an annual rate of 3·3 per 1000, which exceeded by 1·0 the mean rate last week from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had been 21, 20, and 16 in the preceding three weeks, rose last week to 27, of which 14 occurred in Glasgow, 7 in Edinburgh, and 3 in Dundee. The 26 deaths from measles showed a further increase upon recent weekly numbers, and included 14 in Edinburgh and 11 in Glasgow. The fatal cases of scarlet fever, which had been 13 and 8 in the previous two weeks, rose again last week to 12, of which 7 occurred in Leith and 2 in Perth. The 8 deaths from diphtheria, on the other hand, were fewer by 12 than the number in the previous week, and included 4 in Glasgow and 3 in Edinburgh. The 9 deaths attributed to diarrhœa also showed a decline from recent weekly numbers. Three of the 6 deaths referred to "fever" were returned in Glasgow. The deaths returned from diseases of the respiratory organs in the eight towns, which had been 121, 166, and 167 in the preceding three weeks, further rose last week to 181, and exceeded the number in the corresponding week of last year by 60. The causes of 79, or nearly 12 per cent., of the deaths registered in the eight towns were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 27·8 and 32·2 per 1000 in the preceding two weeks, further rose to 33·9 in the week ending Dec. 21st. During the first twelve weeks of the current quarter the death-rate in the city averaged 26·8 per 1000, the mean rate during the same period being 17·6 in London and 20·1 in Edinburgh. The 229 deaths in Dublin showed a further increase of 11 upon the numbers in recent weeks; they included 5 which were referred to "fever," 5 to measles, 4 to whooping-cough, 4 to diarrhœa, 1 to scarlet fever, and not one either to small-pox or diphtheria. Thus the deaths from these principal zymotic diseases, which had been 26, 21, and 13 in the preceding three weeks, rose again last week to 19; they were equal to an annual rate of 2·8 per 1000, the rate from the same diseases being 2·0 in London and 5·7 in Edinburgh. The 5 deaths from "fever" showed a further decline from the numbers in recent weeks; whereas those from measles, whooping-cough, and diarrhœa were more numerous. The deaths both of infants and of elderly persons showed a further increase upon recent weekly numbers. Five inquest cases and 8 deaths from violence were registered; and 81, or more than a third, of the deaths occurred in public institutions. The causes of 32, or nearly 14 per cent., of the deaths in the city were not certified.

"Audi alteram partem."

THE INFLUENZA OF 1847.

To the Editors of THE LANCET.

SIRS,—I observe that influenza is spoken of as an epidemic catarrh, and descriptions of it refer especially to running of the nose and eyes, against which treatment is directed, with the hope of arresting the disease at its onset. Remembering well the epidemic of 1847, I should say that catarrh was by no means a constant symptom, very many persons presenting merely the condition, in a very severe degree, of what is called a feverish cold; and in cases which were fatal by inflammation of the chest-organs there was no initiatory catarrh. Referring to my notes, I find that the first cases which I saw were in November, 1847, in the house of a friend, where a little girl took to her bed with the usual symptoms of pyrexia: hot skin, furred tongue, great prostration, sore-throat, &c. Then all the other children were similarly affected; afterwards the servants, and then the master of the house, who died of acute pleurisy. These cases I thought were gastric fever, but I soon altered my opinion in favour of some specific fever when I found the disease spreading; for other cases soon occurred in the neighbourhood, and in a fortnight afterwards the whole metropolis was involved. The fatal cases were by bronchitis, pneumonia, pleurisy, and pericarditis. The occurrence of the latter was very remarkable, as there was apparently no rheumatic state to account for it. I lost a friend from pleurisy and pericarditis; and a very promising student who had just been examined at the London University died of the same complication. Others of the kind I saw at the hospital, amongst them being the sister of a ward, who, although ailing, had been at her duties in the morning, when, suddenly being seized with a pain at her side denoting an acute pleurisy, she died at night. In none of these cases was there any catarrh. Although the increase of mortality at this time was very great, the percentage of deaths in those attacked was small. It was said that in the epidemic of 1837 half London was attacked, and as regards 1847 I have a note saying it was conjectured that at least three-fourths of the population were affected. The whole of the medical staff at Guy's were in turns attacked, although their illness lasted only a few days, and I remember that on one occasion not a single member came to the hospital to go round the wards or to lecture, so universal was the epidemic. I think it was in 1840 that Henle published his papers suggesting that contagious diseases were due to parasitic life.—I am, Sirs, your obedient servant,

Grosvenor-street, Dec. 21st, 1889. SAMUEL WILKS.

A SIXPENNY INFIRMARY!

To the Editors of THE LANCET.

SIRS,—Referring to your annotation under this heading, and the extraordinary proposal from one member of the medical staff of the Bradford Infirmary that "every patient in the out-patient department shall pay sixpence per visit for advice and medicine," allow me to say that no such proposal has ever been made, or even mentioned, at any meeting of the medical staff or of the board of management. It is true that the out-patient department is overcrowded, and it has become necessary to do something to check those who are not justified in applying. It has therefore been suggested that an officer should be appointed to inquire into the circumstances of all applicants for treatment. This would shut out many who at present impose upon the charity. It has also been suggested that the weekly wage limit which would entitle persons to gratuitous treatment should be for a married couple 18*s.* a week, with 2*s.* additional for each child, and that those families whose incomes are between this—gratis limit—and the present wage

Digitized by Google

limit of the infirmary, which is 18*s.* for parents, with 5*s.* added for each child, should contribute a small sum towards the cost of their treatment. If such patients cannot afford to pay the ordinary moderate fees charged by most medical practitioners, and are still able to contribute something to the funds of the infirmary, I know no sufficient reason why they should not be allowed to do so. These checks would diminish the abuses of the out-patient department without the necessity of creating greater evils, such as provident dispensaries, or the proposed "Public Medical Service." I am anxious to remove the shadow which at present rests upon my colleagues in consequence of such a gross misrepresentation of the above suggestions. If any still remains, it must be upon yours, &c.,

J. H. BELL, M.D.,
Hon. Med. Officer, Bradford Infirmary.

December, 1889.

ANTIFEBRIN IN INFLUENZA OF THE HORSE

To the Editors of THE LANCET.

SIRS,—It may interest your readers to know that the form of influenza now so prevalent amongst horses in London, and which appears very closely indeed to resemble the catarrhal epidemic on the Continent, has in my hands yielded very markedly to the use of antifebrin. I mention this because I observe that some continental physicians strongly recommend antipyrin. As far as I know, these agents have not previously been used in veterinary practice; they appear, however, in the horse to be most valuable febrifuges, being capable of reducing the temperature as much as five degrees in from sixteen to twenty-four hours. An opinion prevails amongst physicians that these medicines, if given freely, are attended with cardiac depression. So far as my observations have extended (and I have treated about 100 cases with antifebrin), in the horse, at all events, no ill effects follow provided that diffusible stimulants be given with the drug, and the latter be withheld on the temperature becoming normal. To show that antifebrin may be given liberally with safety, I may remark that in one extreme case I gave one drachm and a half every six hours for three days, although the pulse was at first very frequent (99) and weak (the standard in the horse being taken as 40). No unpleasant symptoms followed except very slight diarrhœa, which apparently afforded the animal some relief. I could give you a more complete account, but having forwarded an article with cases recorded to the *Veterinarian*, I refer you to this if the subject is of sufficient importance. I feel justified in asserting that antifebrin is one of the best remedies for influenza in horses, that it may in equine patients be given without fear, and that very few deaths will result if good nursing and hygienic conditions are likewise brought to bear upon the patient.

I am, Sirs, yours truly,
W. F. BARRETT, M.R.C.V.S.

New-cross-road, S.E., Dec. 23rd, 1889.

TOOGOOD *v.* WILKES.

To the Editors of THE LANCET.

SIRS,—Naturally, the above action in which I was the defendant, being the first in which the value of the 12th and 13th sections of the New Lunacy Amendment Act has been put to the test, has been commented on by the medical journals. I feel that it is but an instalment of what is due to us as a profession, if we are to do our duty fearlessly and honestly to society. Gradually for many years we have become increasingly a certificating profession. We have to give certificates of stillbirth, successful vaccination, of health to all the public services, public companies, schools, benefit clubs, attendances on juries, sanitation, infectious diseases, lunacy and death. In all, except lunacy, if our certificates are properly given, we hear no more about them. But in my case, although I had obeyed the lunacy laws, it is open to any litigious patient at his discharge from an asylum to accuse me of negligence and wrong in signing a certificate of lunacy, and this without any previous inquiry into the truth of it. The Commissioners of Lunacy, who are both barristers and physicians, appointed by the public to watch over the insane, are not appealed to, though every certificate goes before them for acceptance and confirmation when they visit the asylums. The visiting magistrates and their medical visitor, like the commissioners, are all bound to secrecy, and unless served with a subpœna to give evidence at the trial cannot and do not help you, and in my case, where affidavits only were in evidence, I could not get any assistance from those whose evidence as public officers should be available. It is the wish of every right-minded medical man that the public should be carefully protected, but it is equally a duty that the medical profession should be protected also, and we are not. Why should I have to go through the worry, annoyance, and, I expect, much expense, when I am helping society in its troubles to the best of my ability, spending, as I did, three hours from my home about the patient, being more than an hour with him, and receiving a guinea for my services? Salisbury, a city with about 18,000 inhabitants, has from early in the present century had two large private asylums. Patients are sent from many of the neighbouring counties, and now and then a patient may be brought urgently, with no certificates, or with one, and may be, as in my case, with one of the two, invalid. The medical men resident in Salisbury are thus often called upon to see and examine such patients, and thus experience more of lunacy in their practice than in many a larger city.

The practical bearing of this action will be that the seniors of our profession who have been careful during their lives for the day when they have to retire, and those who have other means, must decline to sign certificates, leaving the public to lose the benefit of their experience and practice.

I wish to express my gratitude to Mr. S. J. F. MacLeod, of the Western Circuit, the counsel, for his able advocacy, and to Mr. G. Smith, the solicitor, for his warm interest and care in conducting my defence in the action.

I am, Sirs, yours faithfully,
Salisbury, Dec. 9th, 1889. W. D. WILKES.

THE STATE OF THE BLACKWATER RIVER.

To the Editors of THE LANCET.

SIRS,—I have been requested by the Farnham Union Rural Sanitary Authority to forward to you for publication the enclosed copy of the report of a committee appointed by them to consider the article of Mr. Haviland in THE LANCET of October 12th last. I beg also to request you to be good enough to insert the accompanying letter, addressed by Mr. Manders, the medical officer of the parish of Frimley, to this authority.

I am, Sirs, yours faithfully,
Farnham, Surrey, Dec. 20th, 1889. G. V. KNIGHT, Chairman.

Farnham Rural Sanitary Authority.

The committee appointed by this authority to consider and report on the article of Dr. Haviland, which appeared in THE LANCET newspaper on the twelfth day of October, 1889, reflecting on the conduct of the authority with regard to the River Blackwater report as follows:—The committee having carefully considered the article of Dr. Haviland, the report of Dr. Lorimer (the medical officer of health of the district of this authority), and also the reports of Mr. R. D. R. Sweeting in 1885, Mr. W. H. Power in 1887, and Dr. Parsons in March last, experts sent down by the Local Government Board to report on the outbreaks of diphtheria, and in the latter case at the formal request of this authority, we beg to call the attention of the sanitary authority to the following extracts from those reports:—1. Mr. Sweeting makes no reference in his report, dated July, 1885, to the River Blackwater as a factor in the outbreak of diphtheria in 1884. 2. Mr. Power in his report dated, April, 1887, states:—

"4. *Emanations from recent deposits of river mud.*—Belief in the dependence of the diphtheria on a cause of this sort appears to have been based on a knowledge that the mud in question was in part (perhaps, indeed, largely) sewage sediment, that the river-cleansing operations and the related deposit of the mud on the river bank had been commenced near to Blackwater Bridge shortly before the outbreak of the diphtheria, and that on a former occasion similar river cleansing operations in this district were remembered to have been followed by an outbreak of diphtheria in their neighbourhood. Added to these facts was the consideration that persons in Yorktown and Camberley attacked by diphtheria must have had special opportunity of breathing this sewage-tainted atmosphere, offensive odours from the dredgings having certainly been wafted very considerable distances. The belief was plausible, and the possibility of such an explanation of the

Digitized by Google

outbreak is not to be denied. But whether or not it furnishes a probable explanation of the facts of the recent diphtheria is another matter. No one advances more than the foregoing general considerations in support of the connexion, and certainly there are some other considerations which do not tell for it, as, for instance, the fact that the quarter of Yorktown nearest, and presumably most exposed, to these emanations by no means suffered most heavily from diphtheria. Thus, not a single cadet out of 300 resident in the Royal Military College (Berks), a few hundred yards distant, suffered from diphtheria, whereas there was a very heavy incidence of the disease upon a considerable number of better class dwellings situated one to two miles from the river, and shut off from Yorktown and Camberley proper by an elevated ridge of land crowned by fir trees."

"1. The outbreak of diphtheria has been found to have been due to milk, though the method of infection of the milk has not, in the present state of knowledge of this subject, been demonstrable."

Dr. Parsons states in his report, dated March, 1889:—

"*Cause undetermined.*—In looking for the cause of the outbreak of diphtheria in November, 1888, we seem to require, in order to explain the first dissemination of the disease, some condition or combination of circumstances first coming into operation about the beginning of November, and acting in a scattered fashion over a somewhat wide area, though exhibiting a preference for certain localities and confined in its operation to persons of the poorer or lower middle class. Such a condition I have not been able to find; possibly it may have escaped notice or have been of a nature as yet unsuspected, or possibly different causes may have been concerned in different cases."

"*Exhalations from river mud.*—Mr. Denny informs me that the bed of the River Blackwater was cleared out last autumn shortly before the diphtheria appeared, and a quantity of weeds and sludge removed. It had similarly been cleared shortly before the outbreak of diphtheria in October, 1886, and Mr. Power, in his report on this outbreak (page 4), mentions that on a former occasion similar river-cleansing operations were followed by an outbreak of diphtheria in their neighbourhood. Probably, however, the connexion is merely one of coincidence. The river is cleansed at the time of year when the water is lowest—i.e., at the end of summer, and outbreaks of diphtheria most frequently commence in autumn. In the present outbreak, as in that reported on by Mr. Power, there has been no special incidence of diphtheria upon houses nearest the river. In the houses in the lower part of Yorktown, near Blackwater Bridge, there was only one case of diphtheria (commencing Nov. 13th), whereas the greater number of houses invaded were at Camberley, a mile away from the river, with intervening rising ground."

We find that the deaths from diphtheria have not been unduly prevalent near the stream of the Blackwater, or on the low-lying lands adjoining. We find that the sanitary authority have carried out the recommendations of their medical officer and of the experts as regards the Blackwater stream. We find from the reports of the medical officer of health and the inspector of nuisances that the Blackwater is in a better sanitary state than it has been for many years past, owing principally to the fact that the adjoining urban sanitary authority of Aldershot have been prohibited from allowing their sewage to enter the stream, and that every effort has been made by the authority to minimise its pollution by combining with the Hartley Wintney Authority in cleaning out the stream, which must always be sluggish owing to its level course and to the soil through which it flows. We find that Dr. Haviland makes serious charges against the sanitary authority, which we consider are without foundation and reflect very unfairly on the authority, and is certainly a reflection on the experts sent down by the Local Government Board to inquire into the causes of the outbreaks of diphtheria.

To the Chairman of the Sanitary Committee of Farnham Union.

SIR,—As the parish of Frimley is bounded on the south-west by the River Blackwater, which has been called the "Foul Blackwater" in an article by Mr. Haviland in THE LANCET, and also forms for four miles and a half part of the valley through which it flows, which has been stigmatised as the "plague-stricken valley," I, as medical officer to the parish, felt it my duty to inquire closely into the sanitary state and general health of the parish for the past ten years, that being the time mentioned in Mr. Haviland's article, and the result of my inquiry as regards this parish is that instead of being plague-stricken, it is one of the most healthy districts in England. It is exceedingly difficult to understand from the article in question whether the middle Bagshot sands is responsible for the plague or the state of the Blackwater river, but the following facts speak well for the district: From August, 1878 (the date of my appointment), until October, 1886, a period of eight years, no death from diphtheria occurred among the paupers or private families under my care in Frimley parish only. For the last eleven years one case of measles, two of typhoid fever, and three of scarlet fever have proved fatal. The deaths have chiefly been due to pneumonia and old age. These figures are taken both from the sick pauper and private families in my practice in the parish. Since the drainage has been finally completed in Camberley and Yorktown only one case of typhoid fever has occurred, and that was proved to have been contracted elsewhere. There have been two outbreaks of diphtheria, the first in 1886, which seemed to have been introduced from Ash, as it first appeared at that end of the parish. In the month of October a great outbreak occurred, nearly eighty cases falling sick within three days; this was definitely proved to have been caused by a milk-supply, and, strange to say, due to one delivery only, that of the afternoon of Oct. 10th, though it was never discovered how that milk became contaminated. This outbreak was confined to the better class of houses, and never spread from the houses in which it first appeared; again speaking well for the sanitation of the district. The second outbreak occurred at the end of 1888, and was at an end early in the present year. This outbreak was entirely confined to the poorer classes, and was chiefly remarkable for the high percentage of mortality, for the number of persons attacked was not great. This attack was traced to infection from the direction of Sandhurst parish, and it should be remembered that at this time a wave of diphtheria passed over London and much of the south and west of England.

Mr. Haviland begins his article by saying that he spent a day in September in this district and found diarrhœa of a severe form prevalent in Frimley, and that the River Blackwater was in a frightfully polluted state. I have in vain turned to my parish register of sick paupers to find corroboration of prevalent diarrhœa—indeed, there is not a single case reported for that month, and only one for the previous month; and surely we should expect to find the complaint among the poorly fed and badly housed, but it was not so; neither was this the case among the better classes, to my knowledge.

The next paragraph states that in certain parishes contiguous to the Blackwater deaths from diphtheria averaged per annum 12·13 to every 10,000 persons living, *when it should have been nil*; but that in the subdistrict of Farnham, which is "out of the influence of the baneful Blackwater," the mortality from this disease was only 4·78. Now, of course it should have been *nil* here, but Mr. Haviland does not tell us the cause of the outbreak in that district. I am of opinion that the Farnham subdistrict being sparsely populated, the disease did not spread so easily, but in the Aldershot district the contagion was the more easily spread owing to the greater density of population.

The statistics of the succeeding paragraph I cannot enter into, as they deal with parishes with which I am not immediately concerned; but the paragraph which deals with the geological conditions of the district shows much want of knowledge of the neighbourhood. "Both diphtheria and diarrhœa can be clearly traced down the stream, their causes acquiring strength as they go, and the pestiferous emanations from its foul water and still fouler banks lie about and overflow into the houses which skirt the valley." So says the article; but if it were correct we should expect to find that the riparian population are the chief sufferers, but this is not the case; on the contrary, at Blackwater Bridge are houses built quite on the banks, whose gardens are frequently overflowed by winter floods, yet no case of diphtheria has been known to have happened in those houses. Any person not acquainted with this part of the county would imagine it to be, after reading this article, a valley closely shut in by heights on either side of the stream, so much so, indeed, that to quote Mr. Haviland, "free flushing by prevailing winds is hindered." This is sheer nonsense, for to the south-west of the stream, in the first four miles and a half of its course, the enclosing heights are nowhere forty feet above the stream; then comes a gap where the Cove brook joins the Blackwater between Farnborough and Hawley, a gap over a mile and a half wide, with not a fifty feet contour between the stream and the heights the farther side of the long valley six miles away. That the parish is protected by the Chobham ridges from the bitter north and east winds is regarded as an advantage by the inhabitants, who always thought themselves open to the genial breezes from the south-west, where the Surrey and Hampshire hills can be seen in the far distance, and lovely views are seen unobstructed by the enclosing heights, which have no real existence.

I have no reason to question the *bona fides* of the writer of this article, but I do wish that any gentleman who may have theories to air about geological formations would spend more than one day in collecting information about the sanitary condition of the neighbourhood before writing articles which carry dismay to everyone concerned in the district, and which may do mischief that can never be undone.

There is no doubt that a few years ago the Blackwater was much polluted. Since then it has been cleaned out. The Government inspectors have reported favourably on the drainage schemes contiguous to it, whose effluents flow into the stream. Since the cleaning out I have frequently seen fish playing about Blackwater Bridge, which would not be the case if it were in so foul a state as it is represented to be.

I have the honour to be, Sir, yours faithfully,

HORACE MANDERS, F.R.C.S.Eng.,
Medical Officer, Frimley Parish.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Notification of Scarlatina with a Vengeance.

AT the City Police Court on the 20th, during the hearing of a summons before Mr. Edward Whitley, M.P., against a boy named John William, living with his parents in the northern part of the city, for playing pitch and toss in the street, a sensation was created. The father, mother, and sister of the defendant were all also summoned for using obscene language to the officer, when he went to the house

Digitized by Google

to get the boy's name. The sister, a married woman, with a child in her arms, who appeared, told the Bench that she had been obliged to leave at home a young child dying of scarlet fever, another child at home was ill, and the baby in her arms had the same disease. The witness became highly excited and fell down in a fit, causing a painful sensation in court. The police officer stated that when he went to the house nothing was said about scarlatina, or he would have reported it at once. The magistrate decided, under the circumstances, to dismiss the summons, and directed the officer at once to report the matter to the medical officer of health. This case shows the importance of prompt notification, the locality from which the cases came being most thickly populated.

A Coroner on the Feeding of Infants.

An inquest was held last week by Mr. Husband, the deputy county coroner, upon the body of an infant three months old, whose mother had died shortly after its birth. The young woman who had charge of it fed the hapless infant between 8 and 9 P.M. on the night of Monday, the 16th inst., with bread and milk "pobbies," and the following morning a little before nine it died, having nothing to eat in the meantime. Mr. Husband condemned this improper feeding, observing that infants of such tender age might just as well be fed on brickdust or sawdust as on strong milk or pobbies. He urged that they should be fed on the best substitute for the mother's milk—viz., condensed milk or cow's milk, weakened, and frequently—at intervals of two hours or so. The verdict was death from natural causes accelerated by improper feeding.

The Assizes.

Mr. Justice Grantham has only just concluded the criminal business of the Assizes here, the calendar having been a very heavy one. Fortunately no prisoner has been left for execution, but there have been several trials for murder and manslaughter, as well as many more for wounding with intent to murder and to inflict grievous bodily harm. Among them was the case of a man charged with the murder of his wife, a confirmed drunkard. In a moment of frenzy, he had cut her throat, inflicting a wound which almost severed her head from her body. The judge observed that the wife's habits could not be considered as a justification for murder, but left the question of this or manslaughter to the jury, who found the more lenient verdict. In another case, in which a man was charged with the murder of his little daughter, of whom he was very fond, it was shown by the evidence of Mr. Kelly; Mr. Cavanagh, surgeon to the Main Bridewell; Dr. Barr, surgeon to Kirkdale Gaol; Mr. Beamish, surgeon to Walton Gaol; and Dr. Joseph Wiglesworth, of the County Asylum, Rainhill, that the unfortunate prisoner was suffering from the milder form of epilepsy, or *petit mal*, at the time of the act. He was therefore found not guilty, and ordered to be detained during her Majesty's pleasure.

Liverpool, Dec. 24th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

University of Durham.

THE Senate of the University of Durham have received a deputation from the College of Medicine, Newcastle-on-Tyne, respecting the proposed connexion of the medical department of Queen's College, Birmingham, with the University, and the arguments were considered for and against the proposal that for degrees in medicine residence in Birmingham shall be counted as residence in the University of Durham. The further consideration of the subject was postponed till the meeting of the Senate in the Epiphany term.

Sunderland Infirmary.

It is stated that the opening of the James Hartley Memorial Wing is to take place on New Year's day. Although the cost of the new wing has been £14,000, it appears that the committee expect to have a clear balance of £700 over and above the cost; and it is intended to hand this over to the infirmary, to help the liquidation of a debt of £3000 which rests on that institution, mostly incurred for certain sanitary alterations. This is indeed a noble record of work done in Sunderland.

North Shields.

A movement is on foot in the borough of Tynemouth for presenting Dr. J. P. (now Councillor) Bates of Morpeth with a testimonial, expressive of the respect and esteem in which he is regarded by all classes as a medical man and a citizen. Dr. Bates was in full practice in North Shields for twenty-five years; and now he has retired to his native place, Morpeth, to rest and enjoy the fruits of his labours. The record of general practitioners thus retiring while yet in health, like Dr. Bates, is not too numerous.

Bedlington.

Dr. Parsons attended at the Local Government Board meeting last week at Bedlington on behalf of the London Board to inquire into the spread of zymotic diseases and the increase of the death-rate in the Bedlington district. He reported having visited several places in the neighbourhood, and recommended improved scavenging and a more improved method in disinfecting houses. He also recommended a trained and qualified nurse for the hospital, and other improvements for the better sanitation of the district, which he thought had improved very little since his last visit, ten years ago. I regret to write that the sanitary condition of Wallsend is also unsatisfactory at present, and an outbreak of typhoid fever is apprehended.

Newcastle-on-Tyne, Dec. 23rd.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

EDINBURGH.

Edinburgh Health Society.

THE last two lectures of the course have been delivered: one by Dr. George Berry on "Popular Ideas and Errors about the Eye," and the other by Professor Chiene on the "Advantages of a Health Society to a Community." They were essentially different in scope and character, but each was admirable in its way. Dr. Berry's points were (1) to minimise the strain on the accommodating apparatus in abnormal eyes as much as possible by early and intelligent use of glasses; (2) not to use poultices, keep the eyes clean, and give them good light and pure air. He mentioned several popular errors in regard to cataract, and gave good advice as to what should be done to avoid injury to the eyes. Professor Chiene's lecture partook somewhat of the character of a *résumé* of the work that has been accomplished by the Society during its ten years' existence. He pointed out the extent to which the community had benefited by the information that had been disseminated by the lectures, reprints, and leaflets. He maintained that there was no law against overcrowding or that it was not sufficiently stringent. He dealt with the necessity of controlling the milk-supply, of inculcating the first principles of hygiene through the Board schools, of sanitary inspection and construction, of compulsory notification of infectious diseases, of precluding medical officers from practice, and of pressing upon the Government the necessity of passing at an early period the Public Health Act, which has been so long on the stocks. Any money spent on sanitation was always well spent. Prevention cost far less than cure, not only in the slums, but in every department in which the public health was involved.

The Influenza Epidemic.

Every person who has a cold in his or her head now feels convinced that at last the influenza epidemic has reached this country. As a rule the patients are so much interested that they are quite elated, and it is only when they learn that they ought to have a headache, no appetite, and very low spirits, or great nervous depression, that their spirits are damped. The weather has done all in its power to prepare matters for the advent of the dreaded epidemic, "exceeding changeableness," "heavy rains," "keen frost," "foggy and disagreeable," "white with snow," "wet and stormy," or "atmosphere thick and murky," "a drizzling rain fell throughout the entire day," follow one another in quick succession in all the weather reports, so that we are quite prepared to find that a few cases of influenza are reported from the hospital of Leith, and that at Burntisland, just across the Forth, several cases of illness,

Digitized by Google

the symptoms of which resemble those peculiar to the Russian influenza, have occurred through the week. The cases were amongst the crews of vessels now in dock, and amongst the *employés* in a mill where oil cake made from cotton seed brought from Alexandria is manufactured. A few sporadic cases and three cases from Dundee are reported. In consequence of the changeable weather above referred to the death-rate in Edinburgh is very high, being at the rate of 23 per 1000, diseases of the chest accounting for no fewer than 50 out of 120 deaths, zymotic diseases being responsible for 24 of the remainder. There were notified during the week 2 cases of typhus fever, 8 of typhoid, 14 of diphtheria, 50 of scarlatina, and 366 of measles.

Christmas Vacation.

The classes rose on Friday, December 20th, and will meet again on Tuesday, Jan. 7th, 1890. During the last week there was no lack of evidence that Yuletide was at hand, the time-honoured kitchen concert in the infirmary, a smoking concert at the Students' Union, and other festive events giving forth that the class examinations were over, and that the last few days, or nights, of the session were to be devoted to good fellowship, after lectures had been attended and other routine work got through.

Edinburgh, Dec. 24th.

GLASGOW.

Election of University Assessors.

The result of the poll in connexion with the election of three assessors to represent the University Council on the University Court is now known. The figures were as follows: Dr. Hector C. Cameron, 1654; Sir John N. Cuthbertson, 1616; Mr. David Hannay, 1372; Mr. Vary Campball, 1038; Sheriff Guthrie, 1036; Dr. D. C. M'Vail, 894. It will thus be seen that the nominees of the University Club, supposed to represent chiefly the senatorial party, have been victorious, while the nominees of the University Council Association, who claim something like a monopoly of reform, are thrown out. A protest against the validity of the election has been lodged on behalf of the unsuccessful candidates, and it is not improbable that the matter will have to be settled in the Court of Session. The grounds of the protest are that the candidates were not properly designated in accordance with law and the commissioners' regulations, and that the registrar, in issuing the voting papers, had failed to state their academic degrees.

University Students' Union Bazaar.

This bazaar has been extremely successful; nearly £14,000 have been raised, while the sum aimed at was £10,000. The union will thus be suitably furnished and amply endowed, and the athletic club and gymnasium will also receive benefit to some extent.

Western Infirmary.

At the annual meeting of this institution held recently, it was stated that during the past year there had been under treatment 12,266 out-door patients, representing 32,743 consultations, as against 13,206 and 35,062 in the previous year. The in-door patients had numbered 4073, as against 3961 in the previous year. The average daily number of in-door patients was 371·17, the greatest number on any one day 404, the smallest 314. Average period of residence 36·61 days; deaths, 316, 8·54 per cent. of all cases treated to a termination. If 76 deaths which occurred within forty-eight hours of admission be deducted, the death-rate is reduced to 6·48 per cent. The infirmary has prospered during the past year financially, and carries a surplus of £6492 to stock account. The number of patients treated to a termination was 3700, as against the previous highest number, 3604. The cost of each bed fully occupied was £51 1*s.* 2*d.*, as against £47 16*s.* 10½*d.* in the previous year, and £49 0*s.* 3½*d.* for the year ending Oct. 31st, 1887. The average cost per patient was £5 2*s.* 5¼*d.*, as against £4 19*s.* 3½*d.* and £4 19*s.* 10*d.* in the preceding two years. The want of a suitable convalescent home at the service of the infirmary is still much felt.

Infantile Mortality in Greenock.

It was stated by an official at a recent meeting of the Greenock Police Board that during the months of October and November the deaths in Greenock had been 217, or 15 per 1000 of the population. Of these, 90, or about 41 per cent., occurred amongst children under the age of five years. The somewhat unusual information was given that scarcely any of these children died in houses of one apartment, but mostly in houses of two or three apartments. It was stated that this infantile mortality was due not so much to hardship of a general kind, as to a laxity on the part of many mothers in the performance of their duties to their children.

Glasgow, Dec. 24th.

Obituary.

DR. ANDREW GRAHAM.

THIS able and accomplished navy surgeon died early in the present month, at his chambers in the Albany, Piccadilly. He was in his seventy-third year.

He came of a family of medical practitioners. His grandfather, Dr. Andrew Graham, originally from Longton, in Cumberland, a scion of the Netherby stock, practised first at Coldstream, and then, at the instance of the Duke of Buccleuch, at Dalkeith, near Edinburgh. After forty years extensive practice in and around Dalkeith, he died in 1824, leaving five sons, four of whom were graduates in medicine in the Edinburgh school. Of these the eldest, Dr. Walter Graham, assisted his father for many years, and died of fever contracted in practice at Dalkeith in 1827. Another son, Dr. William Graham, was for many years consulting physician in Calcutta, and retired to Edinburgh, where he died. A third, Dr. Andrew Graham, practised in the West Indies till his death; and a fourth was Dr. Charles W. M. Scott Graham, who died on May 17th, 1877, after a long and honourable career, of which a narrative appeared in THE LANCET of June 16th of the same year. The subject of the present notice was a son of the eldest of these four physicians, Walter, and was yet a boy when his father died. His education was begun at the Grammar School of Dalkeith, under its able and scholarly rector the Rev. P. Steele, whence he passed, with more than the average share of classics and mathematics, to the University of Edinburgh. At the medical classes he was a diligent and successful student, and in 1837 took the licentiateship of the Royal College of Surgeons, and in the following year graduated as doctor of medicine.

After assisting his uncle, Dr. Charles W. M. Scott Graham, at Dalkeith, for a short time, he entered the navy, first serving in the Mediterranean squadron. He then proceeded to the West India command, and on the outbreak of the Crimean War he accompanied the fleet to the Baltic as surgeon in Admiral Sir Charles Napier's flag-ship. He distinguished himself, in all these waters, as a well-trained and efficient surgeon, admirably cool in danger, and attentive to all the sanitary interests of the crew whether in peace or war. Having served his time, he retired at once, to devote himself to the special studies in medicine which had always possessed a peculiar charm for him, while cultivating, in congenial society, those literary and artistic tastes to which in a quarter of a century's active service he had been able to do but scant justice. In Edinburgh, where his presence was almost as familiar as in London, he will be long remembered as the last and not the least worthy of a medical family which in its day and generation had served the country loyally and well.

Medical News.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen, having passed the necessary examinations, have been admitted by the two Colleges diplomates in Public Health:—

Bailey, Chas. F., M.D. Lond., M.R.C.P., M.R.C.S., St. Bartholomew's, Exminster.
Bampfylde, James, M.R.C.S., Guy's Hospital, Bexley.
Davar, F. Shavaksha, L.R.C.P., M.R.C.S., Bombay, Montague-place.
Harris, Arthur W., M.R.C.S., Charing-cr. Hospital, Holborn Infirm.
Holberton, Henry N., L.R.C.P., M.R.C.S., St. Thos.'s, East Molesey.
Hunter, Wm. Lovell, M.D.Dub., Dublin, Pudsey.
Kealy, John Wm. G., M.R.C.S., King's College Hospital, Forton.
Kempster, Wm. H., M.B.Dur., M.R.C.S., Westm. and Dur., Clapham.
Morgan, G. F. Elliot, L.R.C.P., M.R.C.S., Guy's, Hartlepool Hosp.
Morgan, Wm. Pringle, M.B.Dub., Dublin, Seaford.
Norman, Fredk., L.R.C.P., M.R.C.S., St. Bartholomew's, Brixton.
Paget, Chas. Edward, L.R.C.P., M.R.C.S., St. Barthol., Salford.
Poland, James Harry, M.R.C.S., Guy's Hospital, Littlehampton.

Digitized by Google

Roberts, Arthur, M.D. St. And., M.R.C.S., Manchester, Keighley.
Sylvester, Geo. Holden, F.R.C.S., L.R.C.P., St. Barthol., Devonport.
Taylor, Lot A., L.R.C.P.Edin., M.R.C.S., Birmingham, Brierley-hill.

UNIVERSITY OF LONDON: B.S. EXAMINATION.—**The following gentlemen** have passed the examination for **Honours in Surgery:—**

First Class.—**A. G. Francis** (Scholarship and Gold Medal), St. Bartholomew's Hospital; **C.** McGn. Kitching (Gold Medal), Guy's Hospital; **Robert Devereux** Mothersole, Guy's Hospital; Berkeley **Geo. A. Moynihan, Yorkshire** College.
Second Class.—**Gilbert Benj.** Mower White, University College.

FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—**At the Dece**mber meetings of the Board of **Examiners for the qualific**ation in Public Health the follow**ing medical practitioners**, having passed the necessary ex**aminations, were admitted** as diplomates in Public Health:

Robert Banks, M.B., Rutherglen; Robt. Davidson, M.B., Shettleston; **Andrew J. Hall, M.A., M.D.**, Rothesay; John Hern, M.D., Darlington; **Robert P. Jack, M.B.**, Dunoon; C. J. King, M.B., Pollokshaws; **Jas. Maxwell, M.D.**, Tobermory; John Rowat, M.B., Kilmarnock; **J. Porter Tannock, M.B.**, Greenock; William Whitelaw, M.D., **Kirkintilloch.**

UNIVERSITY OF DUBLIN.—At a meeting of the **Senate held last week the** following degrees were conferred:

Bachelor in Obstetrics.—Robert W. H. Jackson.
Bachelor in Medicine, Surgery, and Obstetrics.—John Donald Alexander, **Wm. Player Kennedy,** Edward Litton Luther, Brendan McCarthy, **Richard McCraith,** Thomas North, Ludovic Perrin, Wm. Stewart **Ross, William Fox Russell,** William Webb Shackleton, Richard Smyth, Gerard William Tate, Robert Henry Woods.
Bachelor in Surgery.—John Simpson.
Master in Obstetrics.—**Charles** Malcolm Moore, H. G. O'Brien (Surg.-Major A.M.D.).
Doctor in Medicine.—**William** Hamilton Allen, Cecil Arthur Digby, **Henry Disney, John Beatty** Hopkins, Joseph Augustus Kane, Elias **William Kerr, John Freeman** Knott, John Agar Matson, Charles **Malcolm Moore.**

SOCIETY OF APOTHECARIES OF LONDON.—**The following candidates, having** passed the qualifying examination **in Medicine, Surgery**, and Midwifery, have received **certificates entitling them** to practise in the same, and were **admitted as Licentiates of** the Society on Dec. 13th:—

Blake, Hubert Elliot, University College Hospital.
Cutler, Lennard, St. George's Hospital.
Hildyard, Nathaniel, University College Hospital.

Passed on the 18th inst.:—

Barber, George Thos. Congreve, Queen's College, Birmingham.
Burton, Wm. Edward, Univ. Coll., Liverpool, Univ. Coll., London.
Du Cane, Edgar, Richmond Hosp., Dublin, Roy. Univ., Dublin.
Jones, Thomas Eyton, University College, Liverpool.
Whitehead, Elihu Theophilus, St. Thomas's Hospital.
Wolfe, Robt. Inglewood, Cork, Leeds, and London Hospital.

On the 19th inst.:—

Marris, William, Middlesex Hospital.
Trist, Hore Browse, St. Bartholomew's Hospital.

SANITARY WORKS, RANGOON.—On Monday Prince **Albert Victor performed** the ceremony of opening the **Rangoon Drainage and** High-pressure Water-supply Works, **which are being constructed** on the Shone system, and are **the first of the kind opened** in India.

DIPHTHERIA AT LAIRG.—The Public School at **Lairg, Sutherland, has** just been closed owing to an out**break of diphtheria at** the railway station and in the **village. The water-supply** of Lairg is suspected as having **something to do with the** outbreak.

NEW MORTUARY, CHESTER.—This long recognised **want has now been provided.** A mortuary has been erected **in Canal-street in the town,** and contains necessary accom**modation for post-mortem** examinations, with other modern **conveniences.**

FEVER HOSPITAL AND INFIRMARY, KILMARNOCK. **Provost McLellan presided** at the annual meeting of this **institution, held on the 19th** inst. The financial statement **showed a total income of** £2786 0*s.* 11*d.*, including a balance **from last year of £638 15***s.*; the expenditure amounted to **£2158 10***s.*, **and there was** a balance in the bank of **£255 2***s.* 1*d.* **after adding** £527 10*s.* to the capital fund. The **capital fund now amounts** to £16,632 10*s.* Four years ago the **total number of cases treated** was 469, while this year the **number is 643. As the a**verage cost of each patient may be **taken at £3 per head, the** annual expenditure in four years **has increased by over £500.** The directors regret to find **that the subscriptions of** the general public and of working **men have this year fallen off,** although trade has been **good; meanwhile the number** of patients has been annually **growing. They sincerely** hope that next year's report will **show increased collections** under all sections of income.

FOOTBALL ACCIDENTS.—Mr. Alfred Miskin, in a football match on the 14th instant, between the St. Albans, Herts, and Apsley End clubs, sustained a fracture of the collar bone. A man named McCormick, during a football match, on the 21st instant, between the Stoke and Burnley clubs, had his leg severely fractured.

SUNDERLAND INFIRMARY.—It has been arranged that the opening of the James Hartley wing shall take place on New Year's Day. Towards the £14,000 required to meet the cost of this addition to the infirmary, as much as £13,858 has been received, and there are promises of subscriptions which will more than make up the deficiency.

MEDICAL MAGISTRATES.—Mr. Henry John Hunt, L.R.C.P. Lond., M.R.C.S., of Sheen House, Harrogate, and Mr. George Banks, L.R.C.P., L.R.C.S. Edin., of Wick, Caithness-shire, have been placed on the Commission of the Peace for, respectively, the Borough of Harrogate and the County of Caithness.—Mr. W. Inglis Mason, L.R.C.P., M.R.C.S., &c., has been placed on the commission of the peace for the borough of Sudbury, Suffolk.

MEDICAL SOCIETY FOR THE NORTHERN COUNTIES. A well-attended meeting of medical practitioners in the North of England, chiefly in Manchester, Liverpool, and Leeds, was held on the 20th inst., at the Queen's Hotel, Manchester, to consider the advisability of forming an Obstetrical and Gynæcological Society for the Northern Counties. Professor J. Wallace (Liverpool) occupied the chair. It was unanimously resolved to establish such a society with centres in Manchester, Liverpool, and Leeds, and a provisional committee was appointed to carry the resolution into effect.

PROVINCIAL HOSPITAL SUNDAY AND SATURDAY COLLECTIONS.—The Norwich Hospital Sunday and Saturday collections for the current year, including the balance brought forward from 1888, amount to £855 4*s.* 10*d.*, against £935 8*s.* 10*d.* the previous year. The annual collection in the Sunday schools of Birmingham and district in aid of the Children's Hospital amounted to £244 14*s.* 11*d.*, which has been handed over to the treasurer of the hospital. The contributions during the past twelve months by workpeople employed at various places of business in the town of Bradford towards the Joint Hospital Fund has amounted to £2250, an excess of £400 on the previous year.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ALBERT, HENRY LOUIS, M.R.C.S., L.D.S., has been appointed Lecturer on Dental Surgery and Dental Surgeon to St. George's Hospital.
CALVERT, W. D., L.R.C.P. Lond., M.R.C.S., has been appointed House Physician to the Sussex County Hospital, Brighton, vice Hodgson, resigned.
COLMAN, WALTER STACY, M.B., M.R.C.P., has been appointed Assistant Physician to the North-West London Hospital, vice E. J. Edwardes, M.D., resigned.
DEANS, W., M.B. Aber., has been appointed Medical Officer for the Edenfield District, Haslingden Union.
FURNER, W., F.R.C.S., has been appointed Surgeon to the Sussex County Hospital, Brighton, vice Jowers, resigned.
GEDGE, A. J., L.R.C.P. Lond., M.R.C.S., L.S.A., has been appointed House Physician to the London Hospital.
HODGSON, G. G., M.R.C.S., L.S.A., has been appointed House Surgeon to the Sussex County Hospital, Brighton, vice Paley, resigned.
JOWERS, REGINALD F., F.R.C.S., L.R.C.P. Lond., has been appointed Assistant Surgeon to the Sussex County Hospital, Brighton, vice Furner, resigned.
MACMAHON, E. J. R., L.K.Q.C.P., L.R.C.S. Irel., has been appointed Medical Officer for the Fourth District of the Northleach Union.
MELLER, CHARLES BOOTH, L.R.C.P., M.R.C.S., L.S.A. Lond., L.M., has been appointed Medical Officer of Health for the Cowbridge District of the Bridgend and Cowbridge Rural Sanitary Authority.
MONEY, ANGEL, M.D., F.R.C.P., has been appointed a Physician to the Guardian Insurance Company.
PHILLIPS, E. A., M.R.C.S., L.S.A., has been reappointed Medical Officer for the Dunham District of the Retford Union.
ROGERS, G. P., L.R.C.P. Edin., L.R.C.S. Irel., has been appointed Medical Officer for the Fourth District of the Greenwich Union.
SAVILE, G. T., M.D. St. And., L.R.C.P. Edin., M.R.C.S., has been reappointed Medical Officer for the Clarborough District of the Retford Union.
THOMSON, THEODORE, M.B. Lond., L.R.C.P., L.R.C.S. Edin., has been reappointed Medical Officer of Health for the Borough of Sheffield.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

BEDFORD GENERAL INFIRMARY AND FEVER HOSPITAL.—Resident Surgeon. Salary £100 per annum, with apartments, board, and washing.

BIRMINGHAM AND MIDLAND SKIN AND LOCK HOSPITAL.—A Third Officer on the Acting Medical Staff.

DERBY BOROUGH ASYLUM.—Clinical Assistant. No salary, but board and residence provided.

DISTRICT INFIRMARY, Ashton-under-Lyne.—House Surgeon. Salary £80 per annum, with board and residence.

GERMAN HOSPITAL, Dalston.—Honorary Medical Officer to the Western Dispensary in connexion with this hospital.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—Surgical Registrar for one year. Honorarium of £40 at the end of the term.

NORTHUMBERLAND COUNTY ASYLUM, Morpeth.—Clinical Assistant. No salary, but board and residence provided.

PADDINGTON WORKHOUSE AND INFIRMARY, Offices, 289, Harrow-road.—Dispenser. Salary £100 per annum, rising by £10 after each year's approved services to £140, together with dinner and tea daily.

ROYAL BERKS HOSPITAL, Reading.—House Surgeon. Salary £80 per annum, with board and lodging.

Births, Marriages, and Deaths.

BIRTHS.

CARTER.—On Dec. 7th, at Broadview, N.W.T., Canada, the wife of Ernest Carter, surgeon, of a son.

CASSIDI.—On Dec. 20th, at Trinity-terrace, Derby, the wife of Francis Cassidi, M.D., of a son.

HUGHES.—On Dec. 17th, at Queen's-road, Wimbledon, the wife of Dr. R. Jaffray Hughes, of a son.

LEWERS.—On Dec. 21st, at Wimpole-street, Cavendish-square, the wife of Arthur H. N. Lewers, M.D. Lond., of a son.

LUCAS.—On Dec. 9th, at Linden Lodge, Gravesend, the wife of George John Lucas, L.D.S. Edin., of Northumberland Chambers, Northumberland-avenue, S.W., of a daughter.

PAGET.—On Dec. 22nd, at Wimpole-street, W., the wife of Stephen Paget, F.R.C.S., of a daughter.

PHILLIPS.—On Dec. 19th, the wife of Dr. Edward Phillips, of Coventry, of a son.

SILCOCK.—On Dec. 23rd, at 52, Harley-street, the wife of A. Quarry Silcock, M.D., B.S. Lond., F.R.C.S. Eng., of a son.

MARRIAGES.

DODD—BARNES.—On Dec. 21st, at St. Saviour's, Preston, Brighton, by the Rev. R. Court Gazeley, many years Rector of Wayford, father of the bride, Walter Harry Dodd, L.R.C.P. Lond., fourth son of Grantham Robert Dodd, solicitor, Highbury, to Emily Augusta, widow of the late Rev. Thomas Barnes, M.A., Rector of Loxton, Somerset, and granddaughter of the late John Alexander, Esq., of Newbury, Berks, and Uphaven, Wilts. No cards.

HUMPHRY—STOKES.—On Dec. 23rd, at Great St. Mary's Church, Cambridge, Laurence Humphry, M.A., M.B., of Trinity-street, Cambridge, to Isabella Lucy, daughter of Sir George Gabriel Stokes, Bart., M.P., P.R.S.

HUNTER—HINE.—On Dec. 19th, at St. Saviour's, Aberdeen-park, Highbury, London, Surgeon C. B. Hunter, 5th Panjab Cavalry, to Agnes Lily, second daughter of the late Henry Hine, of Southampton.

WILLIAMS—FOX.—On Dec. 19th, at the Parish Church, Clifton, by the Rev. Canon Ainger, assisted by the Rev. Talbot Greaves, M.A., and the Rev. Patrick Watson, Patrick Watson Williams, M.B. Lond., 14, Westbourne-place, Clifton, to Margaret Long, daughter of Edward Long Fox, M.D.

DEATHS.

COCKBURN.—On Dec. 15th, suddenly, at Ulverston, Jamieson Cockburn, M.B. Edin., C.M., fifth son of the late George Cockburn, Hope Villa, Alnwick, aged 39.

ROBERTSON.—On Dec. 20th, at 4, Melville-street, Edinburgh, George Gordon Robertson, M.D. Edin., L.R.C.S., aged 75.

ROSS.—On Dec. 24th, at 8, St. George's-place, Brighton, John Harris Ross, M.D., aged 47.

SANDWELL.—On Dec. 14th, Dr. Edward Sandwell, L.R.C.P., M.R.C.S., of Soho-street, Soho-square, aged 51.

SHAW.—On Dec. 21st, at Southsea, Lucy Shaw, for five and a half years a faithful and beloved worker of the North London Nursing Association, 413, Holloway-road.

SIMPSON.—On Dec. 17th, Dr. Harry Ernest Simpson, of City-road, aged 54.

WALTER.—On Dec. 22nd, at Chandos-place, Broadstairs, Odiarne Coates Walter, M.R.C.S., L.S.A., in his 81st year.

WHEELER.—On Dec. 21st, at Osborn House, Putney, Frederick William Wheeler, L.R.C.P., aged 44.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE PROPOSED "PUBLIC MEDICAL SERVICE."

Dr. Hugh Woods writes to state that "Mr. Carpenter is in error in saying that the resolution he quotes was passed at the late meeting of the Metropolitan Counties Branch of the British Medical Association. It was withdrawn, and a vote disapproving only of the section of Dr. Rentoul's resolutions which refers to a "Public Medical Service" was substituted. This was passed almost unanimously. Resolutions were also passed unanimously, asserting the existence of grave abuses in connexion with the hospitals, urging the adoption of a comprehensive scheme for remedying these throughout the country, and also recommending the use of infirmaries and fever hospitals for clinical teaching. The most gratifying feature of the above meeting was the fact that, in the end, differences on minor points were not allowed to prevent united action as regards the all-important questions on which we were agreed."

Mr. R. de B. Saunderson.—The differences in the conditions on which the degrees are granted are so great that they cannot be placed in order of precedence.

Dr. J. Adam (Malling-place).—Yes; it will appear in an early number.

UNQUALIFIED ASSISTANTS.

To the Editors of THE LANCET.

SIRS,—In your issue of the 14th inst. I notice a letter signed "A Young G. P.," in which the writer returns to the old attack upon that much-abused member of the community, the unqualified assistant. He, it appears, would root out the whole class without distinction; but there are many men at present earning a scanty and precarious living as unqualified assistants, who are, I venture to believe, far better fitted to perform their duties than the average "Young G. P." I am unfortunately a member of the abused class myself, and the reason is that I have never been able to procure sufficient means to enable me to pay the necessary expenses incidental to obtaining a diploma. After going through my curriculum and passing my first and second examinations, I got referred in the final (on a purely theoretical subject), and was obliged either to seek some other mode of earning my living, or to pursue the uncongenial vocation of an unqualified assistant. I chose the latter course, and during the eight years that I have been so employed, I have never been able, out of my very scanty earnings, to save sufficient to enable me to present myself again for examination, as, besides the necessary fees for the diploma, I require some time to read, and should either have to employ a coach or attend classes and demonstrations again. After spending much time and money in advancing to this stage of my medical education, it is very unlikely that I should care to relinquish all my future prospects of entering the profession, and consequently I am obliged to take unqualified assistantships; and I know many instances of men who are in much the same position as myself, many of whom will, in all probability, eventually qualify. Since I became fairly proficient in midwifery and the duties of my profession I have often been called in by young practitioners to assist them with some case with which, notwithstanding the dignity and status conferred by their degree or diploma), they had been utterly incompetent to cope, and I have frequently been told by principals that they prefer employing an experienced unqualified assistant to a newly-fledged graduate or diplomate, who knows absolutely nothing of the ordinary routine of practice. I quite agree that men who have never entered the wards of a hospital or received any medical training should be prohibited from practising as assistants, though I hardly see how such men are to be excluded; but to prevent all unqualified assistants from practice would be an injustice both to those already

Digitized by Google

so employed and to their principals. There is too much competition in the profession, and incomes derived from practice are too small in most instances to permit the employment of qualified men, who naturally require a higher scale of remuneration than the unqualified; hence the general practitioner seeks the assistance of an experienced man *sine diploma*. Still I venture to assert that, as a class, unqualified assistants are becoming less numerous every year, and I believe that before long their existence will cease to be a constant source of trouble to their qualified brethren. Hoping that you will find space for my letter, in justice to the class attacked by "A Young G. P.,"

I am, Sirs, yours faithfully,

Dec. 15th, 1889. AN UNQUALIFIED ASSISTANT.

To the Editors of THE LANCET.

SIRS,—I was pleased to see "A Young G. P.'s" letter in THE LANCET of Dec. 14th, and am one with him concerning the too free employment of unqualified men as assistants. And I fail to see of what good the extension of the medical curriculum to five years can be to those who undergo the same and obtain their degrees under more stringent measures. These still will have to battle against the chronic refuse and indolent of the various medical schools, who, unable to obtain even the easiest of degrees through sheer laziness, set themselves up as medical practitioners with the aid of a few members of the profession who, for an easy life and a squaring fee, will do almost anything, no matter how dishonourable or lowering, either because they are wanting in the aptitude or lack the energy of acquiring a practice themselves. I know of one person who has absolutely passed no examination—not even in chemistry—who has a practice of between £600 and £700 per annum. In the same town a second unqualified person attends to cases in a similar manner, but he has an understanding with one of the local medical men, whose aid is sought for in cases about to prove fatal, so as to make sure of the certificate of death. The new Medical Act of 1887 distinctly lays it down that no person can practise unless qualified in the three subjects—Medicine, Midwifery, and Surgery; but still the Act is ignored. Surely the time is ripe to stay this improper practice. We boast a General Medical Council and the Medical Defence Union, yet such frauds are perpetrated on the public, and will be perpetrated so long as we have members in the profession helping the unqualified "Dr." to carry on his illegal trading. Times are hard enough with many of us who have gone to some expense and work to enter the profession, and are we to be shelved by those who have done nothing? The erasure of names from the Medical Register does not appear to act as a deterrent, for there seems to be no diminution, not only in the too free employment of the unqualified, but also in the vast amount of "covering," and I think the time has come for the imposition of a monetary penalty.—I am, Sirs, yours obediently,

Dec. 17th, 1889. ANOTHER G. P.

THE ORIGIN OF THE TERM "PIA MATER."

To the Editors of THE LANCET.

SIRS,—I have been troubled in trying to fathom whence "pia mater" has its original meaning. "Mundinus-Anothomia," printed at Papie, 1478, mentions it, but to account for its being named "pia" we must go further back. I find in Montaigne's Essays, Book II., chap. 12, where he mentions the parts of the body where the ancient writers differently placed the soul, Erasistratus, that celebrated Greek physician, who lived three centuries B.C., places it "adjoining the membrane of the epicranion," and I have not a doubt that it is from this ancient opinion the name has descended to us. I had not been able to discover anything pious about the membrane in question till coming across the opinion of Erasistratus, and should like you to impart the idea to your numerous readers. I am, Sirs, yours faithfully,

South Woodford. EDWIN LITCHFIELD.

THE COMMUNICABILITY OF PHTHISIS.

To the Editors of THE LANCET.

SIRS,—The following facts pointing to the communicability of phthisis may be of interest to your readers.

Fifteen years ago a man with commencing phthisis married a strong, healthy woman of a family free from chest complaints. Soon after this man's death, which occurred in two years after marriage, the woman began to show signs of commencing phthisis. She then married a strong, vigorous man, in whose family there had never been any phthisis, and after some years of married life, during which her chest trouble gradually increased, her second husband began to show the usual signs of incipient phthisis. This week the woman died, and her husband lies in this infirmary with the greater part of his left lung destroyed.

I am, Sirs, yours faithfully,

CHAS. H. TAYLOR, M.B.Lond.,

Infirmary, Derby, Dec. 4th, 1889. House Surgeon.

PERITONITIS AFTER VAGINAL SYRINGING.

To the Editors of THE LANCET.

SIRS,—Dr. Scott Watson relates two cases of the above in THE LANCET of Dec. 21st (p. 1274). In both cases Higginson's syringe was used. If an ordinary female glass syringe be employed, and only two syringefuls injected each time the diaper is changed, the danger of peritonitis from passage of fluid *vid* uterus and Fallopian tube will not be incurred. Condy's fluid, a tablespoonful to a tumbler of warm water, is safer for a nurse to use than corrosive sublimate.—I am, Sirs, yours truly,

Dec. 23rd, 1889. H. F. S.

CORNWALL AS A WINTER RESORT.

Mr. Henry C. Oakshott, F.E.S., in a letter on the above subject, says that much has recently been written in reference to Cornwall, and more especially Falmouth and its neighbourhood, as a winter health resort, and adds that in the interests of the medical profession it is most important that as many details as possible should be brought together with regard to the real winter climate of that county. He accordingly sends as his contribution to the literature upon the subject a list of over 130 plants, &c., being "a few of the more important specimens of wild and garden plants in flower and seed shown at an exhibition held at Falmouth on the 16th and 17th inst. by the Naturalists' Society there." The presence of some of the names in the list is in itself almost, if not quite, sufficient evidence of the extreme mildness of Cornish winters.

M.B.Glas.—The answer is clear that a medical man seeking to recover charges in a court of law, like any other suitor, must give details of his service, and particularly the number of visits paid.

W. E.—It is impossible for us to offer useful advice on the matter. Our correspondent had better be guided by the solicitor whom he has already consulted.

Mr. H. Ison.—We must decline to express an opinion on the nature of a case the complete facts of which are not before us.

Mr. Gerrard.—Next week.

STRANGE EFFECT OF ATROPINE.

To the Editors of THE LANCET.

SIRS,—The following may interest some of your readers. On Dec. 12th a patient aged twenty-one years, suffering from recurrent iritis of a rheumatic character, consulted me. I handed him a small bottle containing liquor atropiæ sulph. (B.P.), with the object of allowing him in my presence to put two drops into the affected eye. Directly he had done so a curious train of symptoms manifested themselves. He at once jumped from the chair on which he was sitting, grasped me tightly, and exclaimed "I am dying." He was unable to stand without support and was very giddy. On removing him outside he was seized with violent twitchings, more particularly in the right arm and leg and in the ligaments around the ankle-joint. The pulse was greatly accelerated. The pupil was slow in dilatation. The twitchings became less severe, and finally disappeared at the end of ten minutes. I may mention that the patient had occasionally used the drug during the past three years without experiencing any ill effects. Since then he has been using a weaker solution, which causes nausea and dryness of the mouth and fauces, but the twitchings have not reappeared.—I am, Sirs, yours faithfully,

EDWARD FRAZER, L.R.C.S.I. and L.K.Q.C.P.I.

Riverstown, Ballymote, co. Sligo, Dec. 20th, 1889.

IRISH PHARMACY AND IRISH FARMERS.

To the Editors of THE LANCET.

SIRS,—Permit me to bring under your notice the existence of a very great grievance under which Irish pharmacists and others labour. I refer to the notorious habit of many Irish dispensary physicians of supplying their private patients with medicines out of their respective dispensaries. Farmers are the chief gainers, while, it is unnecessary to add, more than one class is the loser. I have called the attention of the Local Government Board to the notorious existence of this practice. I hope the matter will be ventilated in Parliament. Their inspectors should ask those dispensary men—they are easily to be found—who supply their private patients with drugs to produce their private invoices, and thus some check would be put on the practice.

I am, Sirs, yours faithfully,

December, 1889. A. B.

THE DISCUSSION ON ANEURYSM AT THE MEDICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—In your report of the discussion on aneurysm at the Medical Society, in speaking of the differential diagnosis of dyspnœa due to direct pressure on the trachea from that produced by paralysis of the crico-arytenoidei postici, I am made to say that in the former instance there is an entire absence of the respiratory excursions of the cords; larynx should be substituted for cords, as it was to the absence of the respiratory movements of the larynx as seen externally to which I wished to direct attention.—I am, Sirs, yours faithfully,

Wimpole-street, W., Dec. 21st, 1889. F. DE HAVILLAND HALL.

A QUERY.

To the Editors of THE LANCET.

SIRS,—I am gradually getting blind, and am awaiting operation for cataract in both eyes. Do any of your numerous readers know of any place where I could be taken in as a paying patient, or of any private practitioner who would receive me on terms to be arranged? If so, perhaps they would kindly address me direct.

I am, Sirs, yours truly,

M. T. MACCORMACK, M.D., Surgeon-Major.

15, Pembridge-place, London, W., Dec. 23rd, 1889.

Remsen, Mr. I., Inorganic Chemistry (review), 743
Renal disease, the density of the blood in, 183; remarkable action of antipyrin in, 431
——— dropsy, on the pathology of, 538
Rentoul, Dr. R. R., the Causes and Treatment of Abortion (review), 796; on hospital out-patient reform and a public medical service, 928, 978, 1033, 1146, 1199; defects in the Manchester system of checking out-patient hospital abuse, 1310
Repositor, new sliding spring, 367
Rescue race, a, 553
Research laboratories, the new, 1357
Resorcin in whooping cough, 923
Retina, pathological changes in the, in cerebral affections, 443
Reuter, Dr. H., obituary notice of, 625

REVIEWS AND NOTICES OF BOOKS.

Lectures on Bright's Disease: by Robert Saundby, M.D.Ed., F.R.C.P.L., 19—Essentials of Physiology: by H. A. Hare, M.D.; Essentials of Surgery: by Edward Martin, A.M., M.D.; Essentials of Medical Chemistry: by Lawrence Wolff, M.D.: Essentials of Obstetrics: by W. E. Ashton, M.D.; Essentials of Pathology and Morbid Anatomy: by Armand Semple, B.A., M.B. Cantab., M.R.C.P.Lond., ib.—Our Library Table, 20, 172, 269, 436, 647, 700, 796, 856, 910—Diseases of the Eye: by George A. Berry, M.B., 74—Psycho-Therapeutics; or Treatment by Sleep and Suggestion: by C. Lloyd Tuckey, M.D., 75—The Bacteria of Asiatic Cholera: by E. Klein, M.D., F.R.S., ib.—Small Text-books of Chemistry, ib.—Transactions of the American Gynæcological Society, vol. xiii., 117—Lectures on Nervous Disease: by A. L. Ranney, M.D., 118—Modern Cremation, its History and Practice: by Sir Henry Thompson, F.R.C.S., M.B., ib.—A Text-book of Pathology, Systematic and Practical: by D. J. Hamilton, M.B., F.R.C.S.E., F.R.S.E.; vol. i., 171—Practicum der Pathologischen Histologie, von Dr. Oskar Israel, 220—The Treatment of Lateral Curvature of the Spine, with an Appendix on the Treatment of Flat-foot: by Bernard Roth, F.R.C.S., 221—Leitfaden für Operationsübungen am Cadaver und deren Verwerthung Beim Lebenden Menschen: von Dr. E. Gurlt, ib.—Papers on Dermatology: by E. D. Mapother, M.D., ib.—The Treatment of Epilepsy: by William Alexander, M.D., F.R.C.S., 268—Archives of Surgery: by J. Hutchinson, LL.D., F.R.S.; vol. i., No. 1, 316—Beitrage zur Pathologischen Anatomie und zur Allgemeinen Pathologie: Redigirt von Dr. E. Ziegler und Dr. C. Nauwerck; vol. iv., ib.—Cosmic Evolution, being Speculations on the Origin of our Environment: by E. A. Ridsdale, ib.—All about Pasadena and its Vicinity, its Climate, Missions, Trails, and Cañons, Fruits, Flowers, and Game: by C. F. Holder, ib.—On Bronchial Asthma, its Pathology and Treatment: by J. B. Berkart, M.D.; second edition, 371—A Text-book of Medical Jurisprudence for India: by I. B. Lyon, F.C.S., F.I.C., 372—Die Chirurgische Behandlung von Hirnkrankheiten: von Ernst von Bergmann, 435—A Guide to the Use of the Mineral Waters of Buxton: by W. H. Robertson, M.D.; twenty-third edition, 436—Buxton, its Baths and Climate: by Samuel Hyde, ib.—A Treatise on Chemistry: by Sir H. E. Roscoe, F.R.S., and C. Schorlemmer, F.R.S.; vol. iii., part 5, 543—Lessons in Gynæcology: by William Godell, A.M., M.D.; third edition, ib.—The Neuroses of the Genito-urinary System in the Male, with Sterility and Impotence: by Dr. R. Ultzmann; translated by Gardner W. Allen, M.D., ib.—Spinoza, "the God-intoxicated Man," a Short Account of his Life and Philosophy: by William Job Collins, B.Sc., M.D., ib.—Sinomia Chimico-farmacotecnica di Salvatore Di-Giorgi, ib.—Mechanics and Experimental Science, Magnetism, and Electricity: by Ed. Aveling, D.Sc., 544—Lectures on General Pathology: by Julius Cohnheim: translated from the second German edition by Alex. B. McKee, M.B. Section 1, The Pathology of the Circulation, 597—The Anatomy of Labour, as studied in Frozen Sections, and its bearing on Clinical Work: by A. H. F. Barbour, M.D., ib.—Syphilis und Auge: nach eigenen Beobachtungen von Dr. Alexander, Dirig. Arzt der Augenheilanstalt für den Regierungsbezirk Aachen, 646—The Physiology of the Domestic Animals, a Text-book for Veterinary and Medical Students and Practitioners: by Robert Meade Smith, A.M., M.D., 699—Inorganic Chemistry: by Ira Remsen, 743—The Elements of Vital Statistics: by Arthur Newsholme, M.D., ib.—Elements of Pharmacy, Materia Medica, and Therapeutics: by W. Whitla, M.D.: fifth edition, 795—Chemistry, General, Medical, and Pharmaceutical, including the Chemistry of the British Pharmacopœia: by John Attfield, F.R.S. &c.; thirteenth edition, ib.—Hints to Travellers, Scientific and General: edited by Douglas Freshfield and Captain W. I. L. Wharton, R.N., F.R.S.; sixth edition, ib.—Father Damien, a Journey from Cashmere to his Home in Hawaii: by E. Clifford, ib.—Medical Handbook of Life Assurance: by J. E. Pollock, M.D., F.R.C.P., and James Chisholm, 855—The Science and Practice of Midwifery: by W. S. Playfair, M.D., F.R.C.P.; seventh edition, 856—Gynæcological Electrotherapeutics: by Horatio R. Bigelow, M.D., 909—A Handbook of Surgical Pathology, for the use of Students in the Museum of St. Bartholomew's Hospital; second edition: by W. J. Walsham, M.B., F.R.C.S., assisted by D'Arcy Power, M.A., M.B., F.R.C.S., 910—A Text-book of Physiology: by M. Foster, M.A., M.D., F.R.S.: Part 2, 957—A Text-book of Physiology: by John Gray McKendrick, M.D., F.R.S.; vol. ii., ib.—A Text-book of General Therapeutics: by W. Hale White, M.D., F.R.C.P., 1010—Studies in Clinical Medicine, vol. i., Nos. 1 to 8: by Byrom Bramwell, M.D., ib.—Hygiene and Public Health: by Louis C. Parkes, M.D., D.P.H.Lond. Univ., 1011—A Text-book of Human Physiology: by Austin Flint, M.D.;

fourth edition, 1066—Handbook of the Diagnosis and Treatment of Skin Diseases: by A. Van Harlingen, M.D.; second edition, ib.—A Dream of the North Sea: by James Runciman, 1067—Étude Critique du Traitement des Salpingites, et, en particulier, du Curettage de l'Utérus dans la Salpingite Catarrhale: par Alexandre Riskallah, ib.—Dermoids or Tumours containing Skin, Hair, Teeth, &c.: by J. Bland Sutton, F.R.C.S., 1120—Watts' Dictionary of Chemistry: Revised and entirely Rewritten by M.M. Pattison Muir, M.A., and H. Foster Morley, M.A., D.Sc., vol. ii., 1121—Annual of the Universal Medical Sciences: edited by Charles E. Sajous, M.D., 1173—Diseases and Injuries of the Ear, their Prevention and Cure: by Charles Henry Burnett, M.D., 1174—Subjects of Social Welfare: by the Right Hon. Sir Lyon Playfair, K.C.B., M.P., LL.D., Ph.D., F.R.S., ib.—History and Pathology of Vaccination: by Edgar M. Crookshank, M.B. [Preliminary Notice], 1232—A Text-book of Human Anatomy, Systematic and Topographical, including the Embryology, Histology, and Morphology of Man, with special reference to the Requirements of Practical Surgery and Medicine: by Alex. Macalister, M.A., M.D., F.R.S., F.S.A., 1233—Egypt as a Winter Resort: by F. M. Sandwith, F.R.G.S., 1234—Manual of Pathology: by Joseph Coats, M.D.: second edition, 1289—Cancer and its Complications: by Chas. Egerton Jennings, F.R.C.S., M.S., M.B., ib.—L'Œuvre de C. J. Davaine—Traité des Entozoaires: par C. Davaine; deuxième édition, ib.—The Asclepiad, No. 24, Vol. VI., ib.—Manuel Pratique de la Garde-Malade et de l'Infirmière, 1290—Irish Medical Practitioner's Guide: by Professor R. J. Kinkead, M.D., ib.—The Victoria Cross; by whom, where, and how won: by T. E. Toomey, ib.—Love of Money the Root of all Evil: by Alec Fearon, 1291—Medical Diaries &c. for 1890, ib.—The Immediate and General Treatment of Accidents and Injuries: by Sir W. Moore, K.C.I.E., Q.H.P., 1337—Clinical Lectures on Various Veins of the Lower Extremities: by W. H. Bennett, F.R.C.S.,,ib.—Madère, station médicale, fixe Climat des Plaines, Climat des Altitudes: par le Dr. C. A. M., Pitta, ib.—The American Armamentarium Chirurgicum, ib.

Revolvers, a tax on, 1130
Reynolds, Dr. E. S., on the so-called presystolic murmur, 976; on fibrinous bronchial casts in the sputum of acute croupous pneumonia, 997; on empyema of the antrum, 1043
Rheumatic periostitis, 1117
—— pyrexia, osteo-arthritis as an immediate sequel of, 947
Rheumatism, acute, the miasmatic theory of, 654; and chorea, 1271; and heart disease in children, nodular periostitis, 265; periosteal nodes in, 1323
Rheumatoid arthritis case of, 1006
Rhinoscopia posterior, a new method recommended for operations in the naso-pharynx, 1112
Rhinoscopy posterior, 555
Richards, Mr. V., obituary notice of, 983
Richardson, Dr. A. J., on antipyrin, 790
——, Dr. B. W., recollections and impressions (medical, hygienic, and general) of the Paris Exhibition, 1077, 1193
——, Mr. D., on the vaccine vesicle, 250
Rickets, excretion of phosphates in, 330; with unusual deformity, 1173
Ricord, Dr. P., obituary notice of, 882; the late, 1091
Rideal, Mr. C. F., the late Albert Smith's works, 941
Ridsdale, Mr. E. A., Cosmic Evolution, being Speculations on the Origin of our Environment (review), 316
Rimmer, Mr. M. C., the Hatton-garden robbery, 1323
Ringworm, hydronaphthol as a remedy for, 1110
Riskallah, Dr. A., Étude Critique du Traitement des Salpingites, et, en particulier, du Curettage de l'Utérus dans la Salpingite Catarrhale (review), 1067
Ritchie, Mr. M., medical advice free, medicine 2*d.* a bottle, 147
Rivington, Mr. W., the recent election at the Royal College of Surgeons, 136; on voting papers at the College election, 191; on stricture of the urethra and its treatment, 531; on Pott's fracture followed by tetanus, 1006
Roaring in horses, 1299
Robben Island leper hospital, 659
Roberts, Mr. C., on diphtheria and acute laryngitis, 738
——, Mr. H. W., the Moon defence fund 1043
Roberts, Sir W., on some practical points in the use of antacid remedies in dyspepsia and gravel, 333; on prophylaxis of uric acid gravel, 909
Robertson, Dr. G. G., death of, 1358
——, Dr. W., on carcinoma of the larynx, tracheotomy, 11
——, Dr. W. H., A Guide to the Use of the Mineral Waters of Buxton (review), 436
——, Sir W. T., obituary notice of, 769
Robinson, Mr. W., Cremation and Urn Burial, or the Cemeteries of the future (review), 856
——, Mr. W. V., presentation to, 576
Robson, Mr. M., on cases of cholecystotomy, 905; on cholecystenterostomy, 1116
Roburite, fatal case of poisoning by, 81; the use of, in mines, 124, 404, 457, 567
Roche, Dr. J., on condemnation of the indiscriminate use of the so-called bronchitis kettle, 833
Rochester, the sanitary state of, 321
Rochford isolation hospital, 868
Rockliffe, Dr., on monocular suppurative iritis, 72
Rogers, Dr. J., the late, the will of, 298
Rollit, Sir A., introductory address at King's College, 693
Romford urban district, health of, 762
Roscoe, Sir H., address on the life work of M. Pasteur, 756; and C. Schorlemmer, F.R.S., a Treatise on Chemistry (review), 543
Ross Memorial Hospital, Dingwall, 348
Roth, Mr. B., on the treatment of diseases of the spinal column, 41; the Treatment of Lateral Curvature of the Spine, with an Appendix on the Treatment of Flat-foot (review), 221; splint for foot-drop, 857
Rotunda Hospital, 501
Roughton, Mr. E., on blood tumours of bone, 1227
Royal Academy of Medicine in Ireland, 938
—— Academy Pictures, 1889 (review), 316
—— Albert Hospital, Devonport, 1153

St. Petersburg, the hot-air treatment of phthisis in, 1133; influenza epidemic in, 1134, 1186, 1194
St. Salvator and St. Leonards, opening of the United College of, 972
St. Thomas's Hospital, 29; introductory address at, 694
St. Vincent's Hospital, inaugural address delivered at the, 1089
Sajous, Dr. C. E., Annual of the Universal Medical Sciences (review), 1173
Salford infectious hospital question, the, 325; isolation of infectious sick at, 751; infectious diseases in, 810
—— Royal Hospital, 799
—— Working Men's Sanitary Association, 773
Salidago virgæ aurea as a diuretic, 660
Saline hypodermic injections in post-partum hæmorrhage, 1024
Salpingites, Étude Critique du Traitement des, et en particulier du Curettage de l'Uterus dans la Salpingite Catarrhale (review), 1067
Salter, Mr. G. H., on case of enuresis of long duration rapidly cured by the use of belladonna, 1056
Salvation army, invalids and the, 1073
Samaritan Free Hospital for Women, 198
Sandell's antiseptic sublimate pelloids, 397
Sanderson, Professor Burdon, 712; theory of asphyxia, 255; on biology, 599
Sandreczki, Dr. M., on the study of leprosy, 423
Sandwith, Mr. F. M., Egypt as a Winter Resort (review), 1234
Sanitary administration, enforcing, 29
—— Assurance Association of London, 1260
—— Congress, the, 663, 716
—— Inspectors' Association, the, 772
—— Institute, the, 298, 761, 1152
—— science, the teaching of, 528
Saundby, Dr. R., Lectures on Bright's Disease (review), 19; on albuminuria, 832
Savill, Dr. T., on cases of hysteria in the male, 792; on the winter climate of the Nile, 995; on myxœdema in a male patient, 1118
Scarborough urban district, health of, 39
Scarlatina, notification of, 1364
Scarlatinal nephritis, fatal, from meningitis, necropsy, 370
—— albuminuria, 1327
Scarlet fever, the spread of, 921; in Plymouth, 82; in London, 749
Scholarships and prizes, 519, 524, 773
School Board problems, 1358
—— closure and measles at Spalding, 866
—— hygiene, 1091; and on medical guidance in the selection of schools for certain children, 889
—— of Pharmacy, 503; introductory address at the, 696
Schools, compulsory games in, 750; insanitary, 1187
Schuhkrafft's crystallised Peruvian bark (or soluble quinquina), 757
Sclerosis, disseminated, 1120
Scotch towns, health of, 40 *passim*
—— Universities Commission, why should degrees in arts not be more accessible to medical students? 1084
—— University degrees, the Home Secretary on, 1127
Scottish ancillary schools of medicine, 508
—— fishery, 443
—— Lunacy Commissioners, annual report of, 546
—— medical schools, 507
—— National Portrait Gallery, the, 127, 582, 633
Scrofulous glands, treatment of, 544, 687

Scurvy, the gastric juice in, 1191
Sea, casualties at, 654
Sea-bathing for children, 445
Seamen's Congress and their grievances, the, 808
—— Hospital, 503; opening of a new branch of the, 132
Seaton, Mr. E., on infectious diseases in London, 720
Selby Oak case, the, 1302
Sellar, Mr. T., presentation to, 98
Semon, Dr. F., on empyema of the antrum, 1043; on laryngeal paralysis, 1120; on aortic aneurysm, 1283
Semple, Mr. A., Essentials of Pathology and Moribid Anatomy (review), 20
Senn, Dr. N., Surgical Bacteriology (review), 701
Senna pods, the therapeutic action of, 164, 252, 1192
Sensational exhibitions, 1074
Septum nasi, a perforation of the, occurring in cement workers, 314
Serous membranes, chronic tubercular diseases of the, 372
Sewage purification, the Amines process of, 601
Sewer air, acute pemphigus resulting from the inhalation of, 791
Sexton, Mr. A. H., Elementary Inorganic Chemistry, Theoretical and Practical (review), 75
Shah, hospital donation by the, 98
Shapley, Mr. H. T., presentation to, 576
Sharp, Mr. E., on the health of the Truro urban district, 619
Shaw, Dr. G., presentation to, 1153
Sheffield General Infirmary, 576
—— Medical School, 506, 759
—— Medico-Chirurgical Society, president's address, 794
—— Pharmaceutical Society, 830
—— Public Hospital and Dispensary, 349
Sheild, Mr. M., a case of cerebral abscess, 1007; on primary tumour of the gracilis femoris muscle, 1059
Shelswell, Mr. C., on case of extensive subcutaneous emphysema following the rupture of a vomica, 1276
Shirtliff, Dr. E. M., on the health of Kingston-upon-Thames, 718
Shooting outrage, a supposed, 1093
Shorthand, for medical students, 94, 935; voluntary examination in, for medical students, 985
Sicherheit, poisoning by, 368
Sidmouth, a cottage hospital for, 773
Sieveking, Sir E., presidential address by, 853
Signalmen's hours, 655
Silcock, Mr. Q., on case of parasiticism by psorospermia, 1279
Silesby, fever and well-cleansing at, 918
Sir Patrick Dun's Hospital, 509
Sixpenny infirmary! a, 1297 1357, 1362
Skin Diseases, Handbook of the Diagnosis and Treatment of (review), 1066
—— eruptions, feigned, 1120
Skull, fracture of, through anterior fossa (?) symptoms of compression, trephining, recovery, 1272
Slater, Mr. C., on spreading emphysematous gangrene, 108
Sleep, prolonged, chorea treated by, 55, 138, 205; the regulation of, 754
Sleeping cars, tuberculosis in, 658
Sleman, Mr. R. R., on a case of mania transitoria, 68; on volunteer ambulance work, 412
Smale, Mr. M., the apprenticeship clause of the Dentists Act, 50
Small-pox, and the Emin relief expedition, 1133; diffusion of, by hospitals, 178; in Jutland, 298; in Venice, 1174
—— hospitals, the Government and, 651
Smith, Dr. A., on treatment of prolapsus uteri by massage and pelvic gymnastics, 116
——, the late Professor Boyes, 1311
——, Dr. F. J., on hypertrophic cirrhosis of the liver, 955; on progressive muscular atrophy, 1230
——, Dr. Protheroe, obituary notice of, 770
——, Dr. R. M., The Physiology of the Domestic Animals (review), 699
——, Dr. R. P., on insanity following mumps, 265; on the effects of sulphonal, 1051
——, Dr. S. C., on gangrenous abscess of the lung treated by incision and drainage, recovery, 113
——, Dr. Walter, on a case of cholecystotomy, 219
——, Mr. H., on ventro-fixation of the uterus, 727; medical fees in life assurance, ib.
——, Mr. J. A., obituary notice of, 673
——, Mr. J. B., the saccharomycete of diabetic urine, 588
——, Mr. N., on practice at the Cape, 941
——, Mr. Priestley, on the size of the cornea in relation to age, sex, refraction, and primary glaucoma, 1062
Smith, Mr. T. S., on large burns, 266
——, Mr. W. T., the diet of lean meat and water, 1201
——, Surgeon-Major J. A., death of, 331
Smoke abatement in manufactories, 1019
Snell, Mr. S., on sarcoma of ciliary body, 72; on the use of the electro-magnet in ophthalmic surgery, 719; presentation to, 773
Snellen, Professor, on symblepharon, ptosis, and episcleritis, 1063
Social Welfare, subjects of (review), 1174
Society for the Relief of Widows and Orphans of Medical Men, 829
Soda water on draught, 865
Solitary and separate confinement, 320
Somerville v. Rose, 974
Sommerbrodt on creasote in tuberculosis, 836
Somnal, 1024
South Africa, medical practice in, 551, 776, 1323
—— London School of Pharmacy, 503
—— Wales branch of the British Medical Association, 33
Southam, Mr. F. A., on the radical cure of hydrocele by excision of the sac, 845; remarks on œsophagotomy for the removal of foreign bodies, with notes of two successful cases, 1325
Southern (America) Surgical and Gynæcological Association, 937
South-Western Fever Hospital, Stockwell, 1086
Sowerby Bridge, epidemic of diphtheria at, 761
Spalding, school closure and measles at, 866
Spanish life assurance company, successful claim against a, 937
—— Medico-Chirurgical Academy, prizes of the, 1207
Spear, Mr. J., report on diphtheria in the Fareham district, 39; report of fatal "croup" in the Horwich registration district, 286; on the sanitary condition of the Hoo rural district, 563; report on typhoid fever at Longton, 1305; report on diphtheria and enteric fever at Penistone district, 1306
Specific morbid poisons, the inter-relations of, 251
Spencer, Mr. W. G., on circumcision, 942; on dislocation of forearm, 1007
Spender, Dr. J. K., on treatment of chorea by prolonged sleep, 138; on osteo-arthritis as an immediate sequel of rheumatic pyrexia, 947
Spina bifida, congenital club-foot and, 1286
Spinal column, the treatment of diseases of the, 41
—— resection, case of, 276
Spinoza, the "God-intoxicated Man," a Short Account of his Life and Philosophy (review), 543
Spleen, removal of, 1055; influence of the, on the bacilli in the blood, 1125
Splenic enlargement and heart dilatation in fever in infancy and childhood, 1166
Spondylalgia, 275
Spondylolisthesis, case of, 116
Sponge electrode for general faradisation, a new, 270
Sponge-holder, a new form of, 174

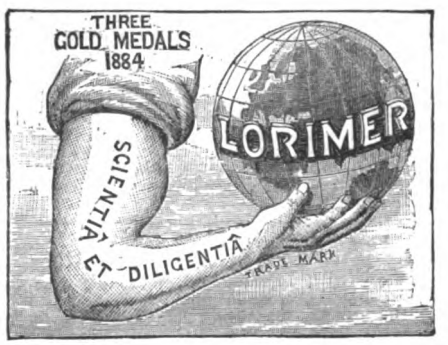
ASTHMA, CURED BY ROSSITTI'S FERROUSITE ASTHMA.

Dr. J. Rossitti, Chemist, 76, Strand, London, W.C.

Sir,—I have much pleasure in informing you that your Ferrousite Asthma Cure has proved most successful in my case. I have suffered from Asthma for the last 20 years, and have tried many remedies, but your Ferrousite Asthma Cure is the only one that has done me any good. I have taken it for a month, and am now free from Asthma. I shall be pleased to recommend it to my friends.



Yours faithfully, (Signed) JOHN HOLLAND.

Price 2s. 6d. per bottle, by post 2s. 9d. Sold by all Chemists, or direct from the Proprietor, J. ROSSITTI, Chemist, 76, Strand, London, W.C.

Ozone Cigarettes are also made in Cigarette Holders, and are sold in packets of 10 for 1s. 6d., and boxes of 50 for 6s. 6d. Ozone Cigarettes are also made in Cigarette Holders, and are sold in packets of 10 for 1s. 6d., and boxes of 50 for 6s. 6d.

Prepared by R. ROSSITTI, Chemist, 76, STRAND, LONDON.

LORIMER'S COCA WINE

Has risen to first importance in the Medical Profession, and become almost as well known as "Port" or "Sherry," for either of which it is a most wholesome substitute.

It is a powerful MUSCULAR, NERVE, and VOICE TONIC, giving unusual power of endurance in both mental and physical labour; it is also remarkable in its food-replacing power, persons being able to abstain from food for many hours after a full dose of this Wine of Coca.

Sold in Bottles, 3/6 each; per dozen, 36/-

LORIMER'S "SYRUP HYPOPHOSPH. CO. LORIMER'S." HYPOPHOSPHITES.

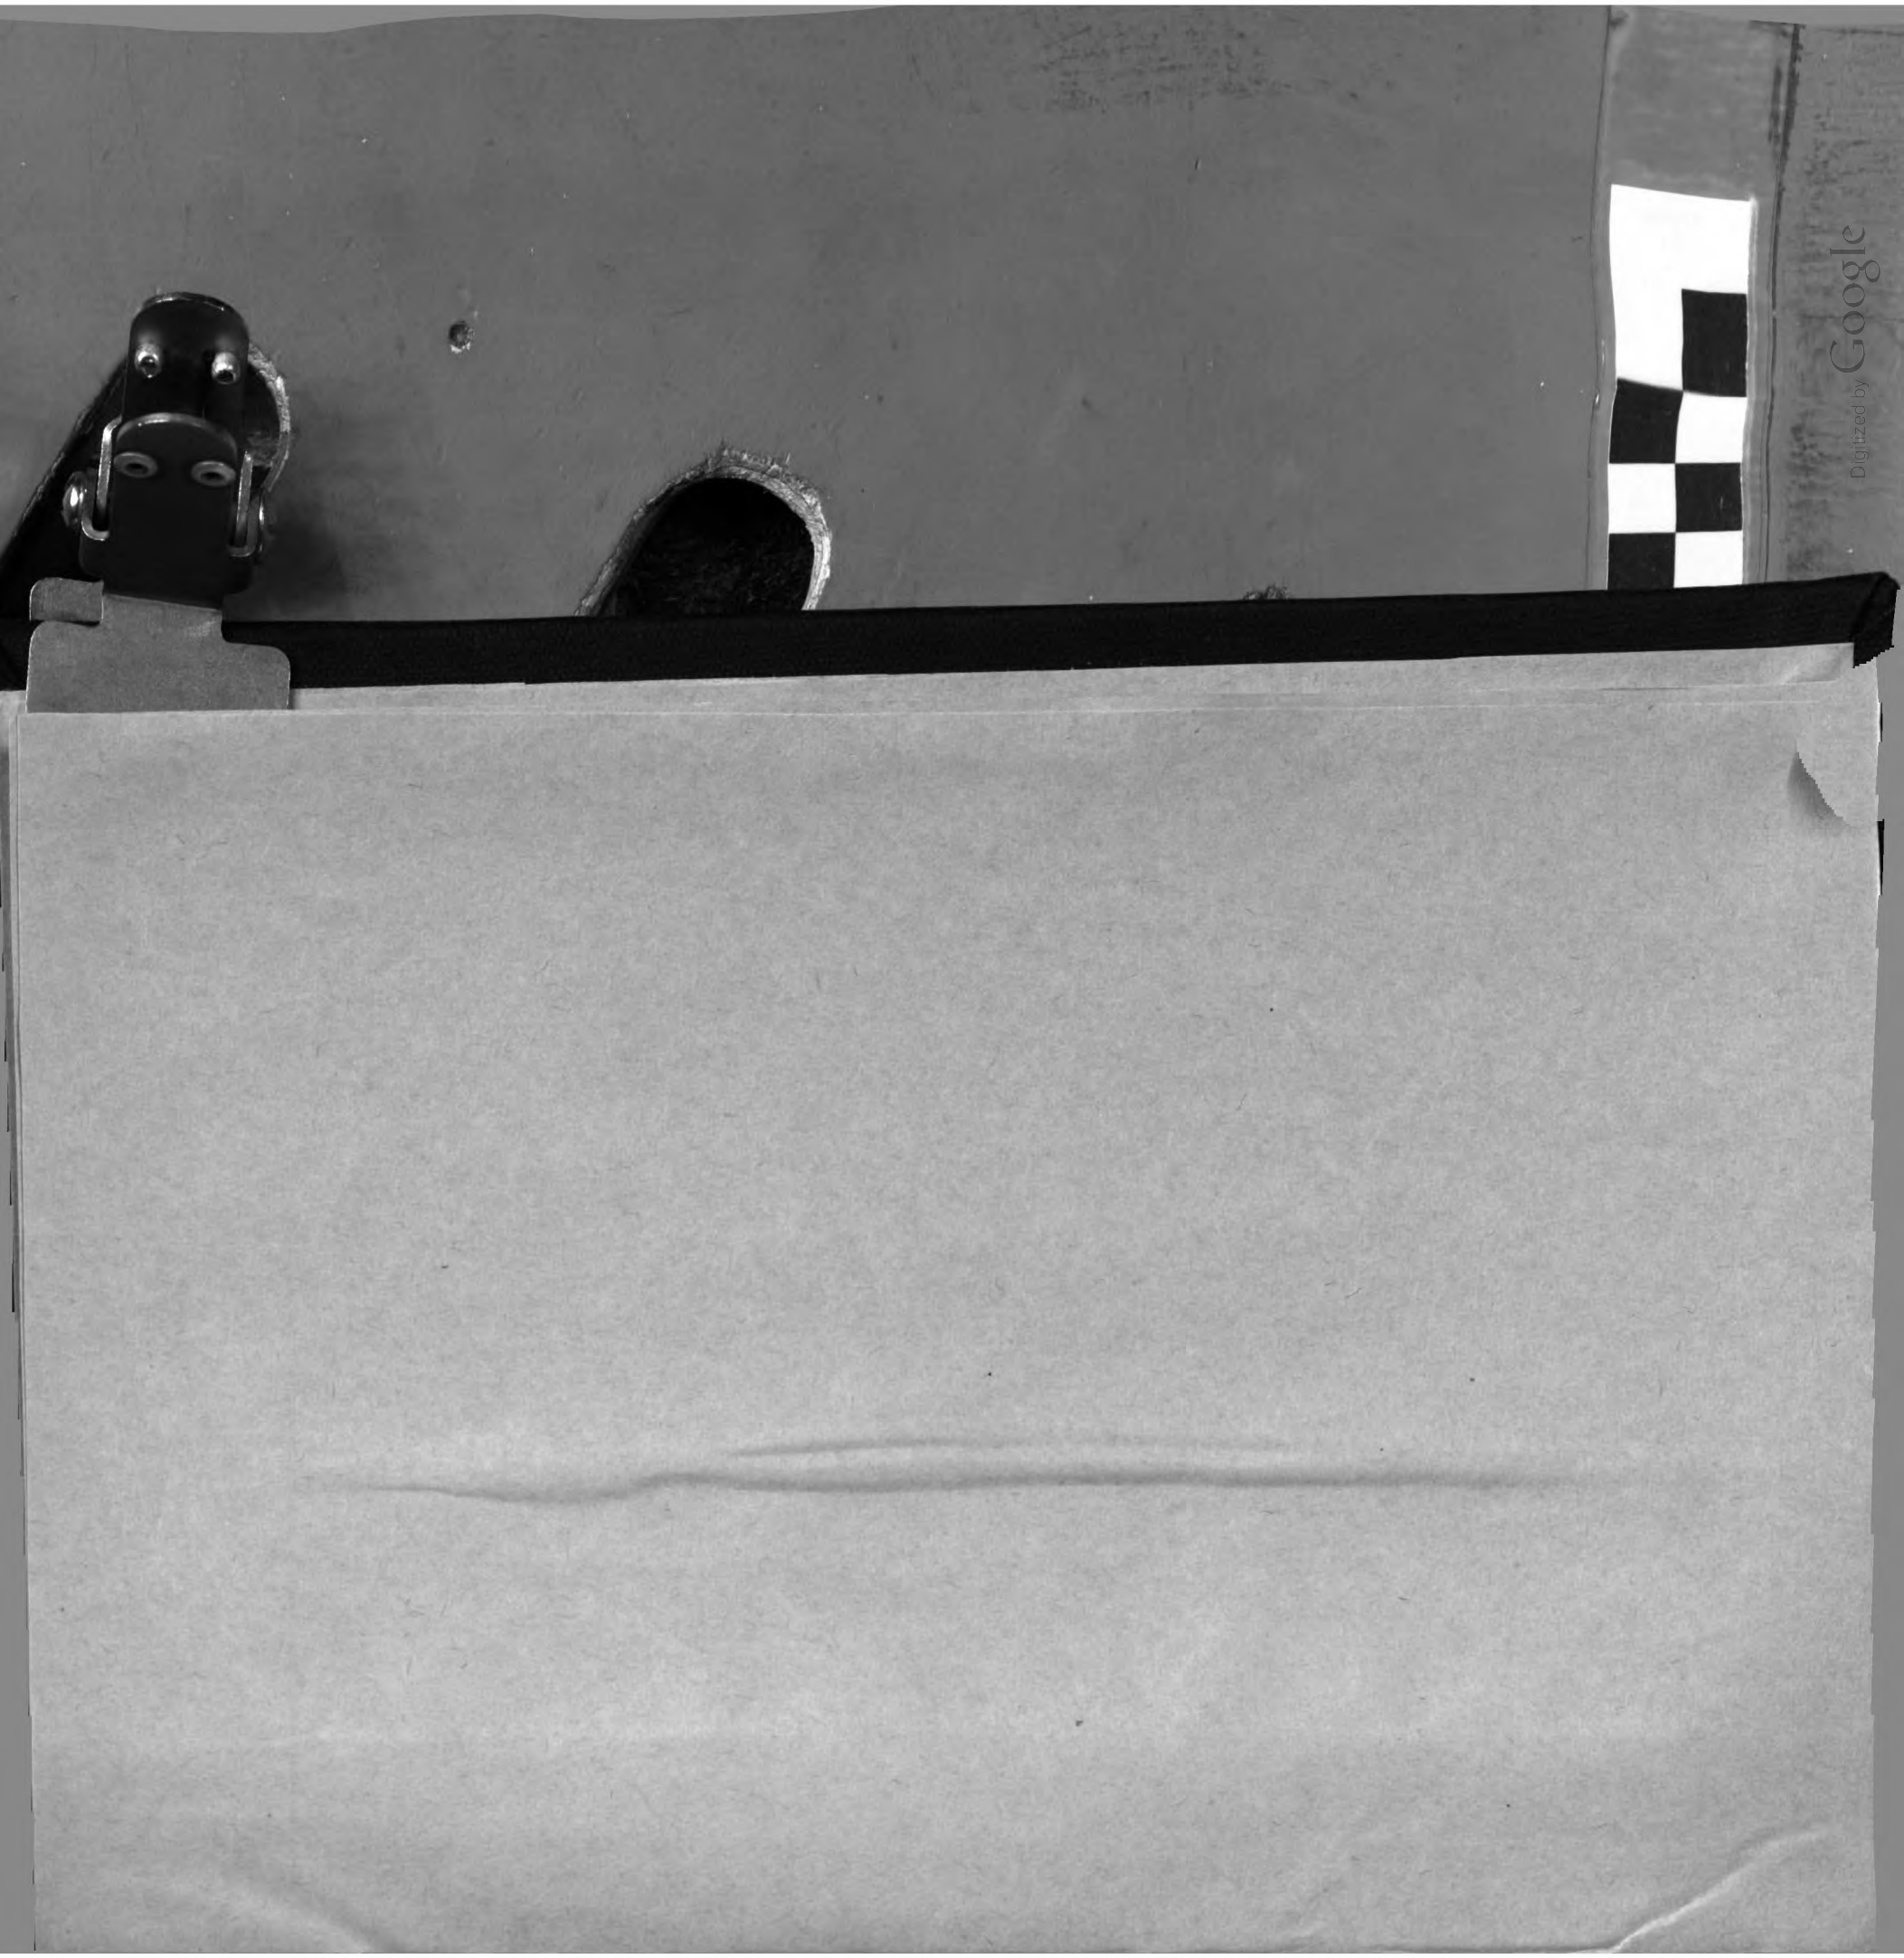
NEUTRAL or very slightly alkaline.

DEFINITE, Original, and stated Formula *(see Label).*

PERMANENT. Does not deposit its active ingredients.

PRICE MODERATE. Deserving and receiving the support of the Medical Profession.

Sold in bottles, ½-lb. & 1 lb., 24/- and 42/- per dozen. Unstamped, for dispensing, 21/- and 36/- per dozen.



WRITE FOR PRICE LIST OF LORIMER'S SPECIALITIES.

LORIMER & CO., BRITANNIA ROW, LONDON, N.
